**BACON.**—Curers have had a very busy month, the shortage in pigs making it difficult to supply all trade wants. Best factory-cured sides sold at 9½d. to 10½d.; lard in skins, 8½d.; bulk, 7½d.. Hams met with the usual seasonable inquiry, with good rates, 11d. to 1s. ruling throughout; well cut and cured farm middles and hams, 8d. to 10d.

**HONEY.**—Although heavier quantities of new season's take are coming forward, the active demand has readily cleared all lots of prime clear extracted at 2½d. to 3d. per lb., but second grades are rather slow of sale. Beeswax, 1s. 2d. to 1s. 3d. per lb.

**ALMONDS.**—Last season's crop is exhausted, and buyers are now waiting the arrival of the new, which is likely to open out at good figures. Quotations:—Brandis, 7½d.; mixed softshells, 7d.; hardshells, 4d.; kernels, 1s. 6d. to 1s. 7d. per lb.

**LIVE POULTRY.**—The forwardings have been most extensive and much heavier than experienced for many years, no doubt the scarcity of green feed and the high price of wheat causing many farmers to sell rather than pay such high rates for feeding their birds. Values throughout the month were very good when quality was right; medium and light birds sold according to condition; nice prices are anticipated at the commencement of the new year. Heavy-weight table roosters brought 3s. 6d. to 4s. 10d. each; nice conditioned cockerels, 2s. to 3s.; plump hens, 1s. 4d. to 1s. 10d.; small and light, 1s. to 1s. 3d.; ducks, 1s. 8d. to 3s.; geese, 4s. to 7s. 3d.; turkeys, from 6½d. to 1s. 1½d. per lb. live weight for poor to prime table birds.

**POTATOES AND ONIONS.**—Local supplies of potatoes have been consistently short of trade requirements, and substantial quantities have been imported from every Commonwealth State except Queensland. Onions are in fair supply, although a few tons have been purchased from Victoria. Quotations:—Potatoes, 13s. per cwt. in the market; onions, locals, 12s. per cwt. in the market; Victorians, 14s. per cwt. in the market.

# RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of December, 1914, and the average annual rainfall.

| Station.                   | For Dec., 1914. | To end Dec., 1914. | Av'ge. Annual Rainfall | Station.               | For Dec., 1914. | To end Dec., 1914. | Av'ge. Annual Rainfall |

\* No report received during the month of November.

† Formal report only received.

‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

### February 10th, and March 10th, 1915.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

Edited by GEORGE G. NICHOLLS, Secretary Advisory Board of Agriculture.

#### UPPER-NORTH DISTRICT.

(PETERSBURG AND NORTHWARD.)

MORCHARD (Average annual rainfall 11in. to 12in.).

October 31st.—Present: eight members and one visitor.

FODDER CONSERVATION.—In a short paper on this subject Mr. B. S. McCallum said that the short hay season in this district made it somewhat difficult at times to handle the cut, therefore it was well for farmers to turn their attention to ensilage. Green stuff for the silo could be cut before the hay harvest commenced, and could be stored immediately. Fodder conserved in this manner was especially suitable for dairy cows, cattle, and sheep. Another practice that should receive attention was that of cutting portion of the crop with the binder, and then thrashing out the grain. Wheaten chaff from the strippers and harvesters should be saved, and when practicable a small plot of lucerne should be grown under irrigation. Members were generally agreed as to the wisdom of caring for the cocky chaff, and also cutting portion of the crop with the binder. Mr. J. W. Riechstein had not been successful in his attempts to grow sorghum; but agreed that it paid to grow lucerne where water was available for irrigation purposes. Mr. B. S. McCallum advised cropping portion of the stubble to provide fodder for ensilage.

MORCHARD (Average annual rainfall, 11in. to 12in.).

November 28th.—Present: seven members and eight visitors.

CAROB.—Mr. W. Toop read a paper in which he referred to the value of this tree. It was a native of the countries bordering the Mediterranean, he said, and a leguminous evergreen. It was readily eaten by stock, the beans which it produced being of chief value. It also made splendid shade, and afforded a good breakwind. It should be planted about August from the beans, which should be first soaked in boiling water for about 12 hours. The plant was a splendid drought-resister, and would live for a great number of years, and grow in most soils. Fowls and pigs would readily eat the beans. Members discussed the paper. Mr. E. J. Kitto thought the lucerne tree more suitable than the carob, as the latter was very slow in maturing. Mr. B. S. McCallum had failed to grow the carob; the frost killed it when young. Mr. R. Jasper (Chairman) mentioned the feeding value of the beans for pigs and stock.

WIRABARA (Average annual rainfall, 18.91in.).

October 3rd.—Present: 20 members and one visitor.

DRY FARMING.—Mr. A. R. Woodlands read a paper under this heading. The subject of soil moisture and moisture conservation, he said, was one of the most important with which the agriculturist and horticulturist had to deal. In many instances fallow was turned up in large lumps, late in the spring, and then left

throughout the summer. The result was that at seeding time the fallow was devoid of moisture, and crop failures followed. He emphasized the value of fallowing early and deeply, with plenty of working during the spring and summer to a depth of 3in. Early wheats did better in dry seasons than late varieties. Farmers should experiment and select the most suitable varieties for their different districts.

WILMINGTON, December 2nd.—Mr. E. McGhee contributed a paper dealing with the care of vehicles and harness. The paper gave rise to an interesting discussion.

### MIDDLE-NORTH DISTRICT.

(PETERSBURG TO FARRELL'S FLAT.)

BEAUFORT.

October 29th.—Present: 11 members.

THE HEADER.—Mr. C. W. Veitch read a paper. If farmers cut, say, 50 acres to 70 acres each year with the binder, and put this through the header, he said, enough straw would be conserved to tide over bad times. He considered that practically the same amount of grain was obtained by using the header as by reaping and cleaning the stack, although the header entailed a little more work. This machine would cost about £82, with an additional £15 for an elevator to carry the headed straw on to the stack. It would be a good plan for three or four farmers to co-operate in the purchase of one. A lengthy discussion followed the reading of the paper. Mr. P. H. Underwood did not think the header was profitable, as it would only return about half the wheat, and also the sheaves were badly knocked about. Binding for the header left no feed in the paddocks. Mr. J. Sampson considered that it would be useless to try to head this year, as the sheaves were too short. The Chairman (Mr. W. W. Mugford) recommended the header for saving straw. He favored co-operation for the purchase of such a machine. Often, in good seasons, there were rank crops, which, if left to ripen, would deteriorate; but with the header this would be avoided. He thought headed straw was almost as good as hay. Messrs. G. Underwood, S. Underwood, J. Marr, the Hon. Secretary, and A. Yard favored the header. The last-named gentleman considered that better grain was obtained through the header than by using the stripper.

CANOWIE BELT, November 3rd.—Mr. Schultz read a short paper in which he advised farmers to have a small piece of land set aside for a vegetable garden, to supply the household wants. Plenty of attention would have to be given, and a well for irrigating would be necessary. A fence should be erected to keep the poultry off the garden. He recommended digging out the soil to a depth of 18in., and then filling in with alternate layers of earth and manure. On frosty mornings the plants should be sprinkled to save them from frostbite. Members generally agreed with the paper. A paper on "Mixed farming," read at the Annual Congress by Mr. A. L. McEwin, of the Blyth Branch, was read by Mr. H. A. Wedding (Hon. Secretary) and discussed by members.

### LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

NANTAWARRA (Average annual rainfall, 15.90in.).

October 1st.—Present: seven members.

STRIPPER v. HARVESTER.—Mr. W. Greenshields read a paper under this heading. He mentioned the saving of cocky chaff that was effected by the use of the stripper. In some instances a carrier was attached to the harvester, but he did not favor this, as the heads were thrashed and rethrashed, and the backbone was thrown into

the chaff. Also on windy days much of the chaff was lost. Again, the carriers caused much wear and tear to the harvesters and more draught was required. Where it was intended to bind the straw it was preferable to use the stripper, as this machine did not knock as much straw down as did the harvester. In discussing the paper Mr. A. F. Herbert said that he preferred the harvester with carriers for working heavy crops, but for this season he favored the stripper. Mr. Sleep favored the stripper on account of the saving of the cocky chaff. The harvester scattered the seeds of the weeds too freely, which later on became hard to cope with. Messrs. Dixon and Sutton favored the harvester for heavy, and the stripper for light crops; but Mr. Sutton did not think that the weeds had been so difficult to deal with since the advent of the harvester as before. Mr. J. H. Nichols mentioned that to secure good, clean straw he preferred to have a binder and stripper working simultaneously in opposite directions, passing at the corners. With regard to the seed scattering of the harvester, he thought that in view of the system of cropping every third year, this would be beneficial in providing feed in the stubble.

#### TWO WELLS (Average annual rainfall, 16.36in.).

December 1st.—Present: seven members.

**SHEEP ON THE FARM.**—Mr. G. M. Cordon read a paper. A few sheep on the farm, he said, did not require much attention. The farmer should select his breed and obtain the best of that class, of course the carrying capacity of his holding would determine the number. Stores bought in January and marketed in September of this year showed a profit of from 10s. to 11s. per head. Sheep also cleared the land of all weeds, and at the same time enriched it. They could also be turned on to crops that were showing too strong a growth. He did not recommend keeping them on the farm for wool production alone, and deprecated the practice of over stocking. It was much more profitable to keep a few, and always have them in good condition. Lamb-raising would be found profitable—a few months back prime lambs brought as much as £1 per head. He did not think the breed counted for much in lamb-raising. Shearing should be done at the end of September or the beginning of October. The fleeces should be skirted, and the locks and bellies kept separate. About three weeks after shearing the sheep should be dipped. In discussing the paper Mr. Kenner considered that cows would pay the small farmer better than sheep. Forty-five cows in this district had produced milk to the value of £500 in 12 months. Mr. Pratt favored keeping sheep, as this did not involve so much labor as keeping cows. He would keep one breed, as mixing the breeds decreased the value of the fleece. He favored the Comeback ewe crossed with the Border or English Leicester ram. The lambs from this cross did much better in hot weather than most others. It was important that the ram be pure bred.

#### WATERVALE (Average annual rainfall, 27.17in.).

September 28th.—Present: 11 members.

**FENCING.**—Mr. A. S. Davis read a paper describing his method of constructing cattle and sheep-proof fences. For the former, he said, split posts about 5ft. 6in. to 5ft. 9in. long (according to nature of the ground) and 4in. by 2in. at small end should be used. The height of the fence should be 3ft. 9in. He preferred four wires—three plain and one barbed. The bottom wire should be 14in. from the ground, second 23in., third (the barbed wire) 33in., and the top wire 43in. The barbed wire should be run through the posts, which should not be more than 10ft. apart. Strainers 7ft. 6in. long x 12in. at small end, should be placed at each distance of 110 yards. For a sheep-proof fence the posts should be 5ft. 6in. long, 5in. by 4in. at the small end, and placed about 30ft. apart, with two droppers between. This fence should have five plain and one barbed wires, spaced as follows:—Bottom wire 6in. from ground, second wire 12in., third wire 18in., fourth wire 25in., fifth wire (barbed) 33in., and top wire 41in. from the ground. The barbed wire should be run through the posts as in the other fence, the strainers being placed at 110yds. apart. Members discussed the paper.

**CLARE, October 30th.**—Mr. D. Menzie gave an address on agriculture in Java. He made reference to the three main products—rice, sugar cane, and rubber—and

explained the method of cultivation. Rice was the principal product. He referred to the great possibilities of Northern Australia, where conditions were very similar to those of Java for the growing of these products. In reply to a question Mr. Hicks stated that he had rung his currant vines this year, and the fruit had set excellently. He considered it advisable to ring vines which showed vigorous growth.

**SALISBURY**, November 3rd.—The meeting was attended by Veterinary Lecturer (Mr. F. E. Place, B.Sc., M.R.C.V.S.), who gave the first of a series of four lectures to this Branch.

## YORKE PENINSULA DISTRICT.

### (TO BUTE.)

**BUTE** (Average annual rainfall, 15.42in.).

October 29th.—Present: nine members.

**PIG-RAISING.**—In a paper dealing with this subject Mr. J. J. Trainer said:—"In introducing this subject the fact places itself before all of us that, under ordinary circumstances, conditions which have normally existed during the last 10 years in this district do not offer such facilities for raising pigs as may be the case in other localities. I shall consider the position as if a market were in close proximity. Some breeds mature quickly, others are slow; some are reared for hams, others for bacon, and so on, always being ruled by the market. The breed mostly seen in Australia is the Berkshire, although several others are now becoming more evident. The Berkshire is perhaps the more popular because of its general hardiness. It can stand the hot sun better than most breeds, is thrifty, fattens readily, and the flesh is of good quality, with fair distribution of fat and lean. However, the best breed is a matter of opinion, and I shall not dwell on that point. I found the Berkshire-Yorkshire cross good and very profitable pigs. Under natural conditions the pig is a grazer. Better pork is obtained from the animal which is run in a small paddock, and sty-fed at the last, than from that which is sty-fed throughout. Sties should be airy, but not draughty. They should be in such a position as to be open to the morning sun, and should be well drained. Bedding is necessary when the weather is cold, and especially for the sow at farrowing time. Feeding will vary somewhat according to the age and state of the pigs. Milk forms a valuable part of the animal's ration. All grain should be soaked, and is still better if crushed and soaked. The pig relishes a moist diet rather than a dry one, and will give better returns for the same food after soaking a few hours than when fed dry. The old practice of permitting the feed to ferment and become a source of annoyance on account of the offensive odour it gives off is no longer followed by the intelligent feeder. The sow's diet for a week before farrowing should be of a soft, sloppy kind, such as crushed grain or pollard, and some green feed of any kind; but no hard or dry feed should be given. The same course should be followed for a week after farrowing. Young pigs should be fed well from birth, if the object is simply to sell the animal when fat. Above all, do not allow the animal to fall away at any stage of growth, since it must be brought at an increased cost of food over that originally required to bring it to the condition at which it began to fail. The breeding sow should not be kept too fat. Pigs of all ages should have access to plenty of water, troughs being kept clean by daily washing. Too much attention cannot be given to the selection of breeding stock, as a false move in the selection of the boar especially will affect a great number. Select from reputed and long-established stock. Pure-bred pigs should be chosen. See that the sexual organs of the boar are well developed. The breeding animal should be of a large litter. See that the sow's teats are well developed. There should be 12 or more. A boar should be first used when eight or nine months old, according to the breed, and the sow should be put to the boar when nine months old. The period of a sow's gestation is 16 weeks. The sow when near farrowing should be kept away from other pigs, as she is liable to be injured. Plenty of short bedding should be allowed. If the straw is long young pigs are apt to get lost and injured. The sow

generally farrows without any serious after-effects. Two ounces of sulphur and a little nitre will help the sow if she is at all constipated, and a little exercise every day will also do much good. Generous feeding is required, or all will suffer. The time for weaning will vary a little according to circumstances, but from seven to eight weeks will generally be found most satisfactory. A sow comes in season about four or five days after the pigs are weaned, about 10 to 14 days after that, and then every three weeks regularly. Under ordinary conditions a sow will rear two litters a year. Young boars can be castrated when four weeks old. In castrating a ruptured pig great care must be taken, and in every case the incision must be sewn up. Feed the young pigs at short intervals; they fatten more quickly and do not waste so much as is the case if fed less frequently and given bigger feeds. A fat pig will dress up to 90 per cent. of good meat, and will weigh 10 or 11 times the weight of its head." A discussion followed, in which Messrs. Bettos, Matthews, Hall, Commons, and Barnes took part.

YORKETOWN, December 12th.—Several members stated that they intended testing high grade super. during the coming season. Mr. Correll exhibited a labor-saving device for supplying poultry with clean drinking water.

## WESTERN DISTRICT.

### CARROW.

November 5th.—Present: 15 members and four visitors.

SMALL PRODUCTS OF THE FARM.—Mr. T. Burt (the Hon. Secretary) delivered a paper dealing with the care and value of byproducts of the farm. Sheepskins, if kept free from dirt and blood, dried, and handled with care, he said, would return much more than if carelessly thrown over a wire or rail in the sun. When the skins were to be kept for any length of time before being marketed, they could with advantage be painted with the following preparation:—One tablespoonful of arsenic, 1in. from a bar of common washing soap, two tablespoonfuls of washing soda, boiled until dissolved, in one gallon of water. Should this become solid when cold, sufficient hot water to make a free liquid should be added. Another matter that could receive attention was refuse fat, which, if collected in an old tin, would frequently, in exchange, secure sufficient soap for the needs of the household. Egg production should receive attention, and he advised farmers to sell their eggs, and not barter them for goods. Mr. T. Beare advised farmers to keep only young fowls. Mr. Matthews described a serviceable method of packing eggs for market. Messrs. J. McBride, Freeman, and Ancar also spoke.

COORABIE (Average annual rainfall, 11in. to 12in.).

October 3rd.—Present: nine members.

HOMESTEAD MEETING.—The meeting was held at the homestead of the Vice-Chairman (Mr. V. S. Kinsley), whose farm was inspected by members. In consequence of the unfavorable season the crops did not look very promising. Those on the lighter soil (scrub land) appeared to be standing the dry conditions better than those on the firmer soil of the plains. A crop of Big Bulkhead on the former came in for favorable notice; as did a well of water containing only 1-5oz. salt per gallon. The experimental plots were unfortunately too backward to afford much opportunity for comparison, but they showed evidence of methodical and careful working. The good condition of the implements and machinery proved to members the value of an occasional coat of paint and of prompt attention to breakages, &c. A 4-cylinder petrol engine used for driving the chaffcutter, grinding mill, and circular saw, attracted attention. The pigsties contained some very good Middle Whites and Poland-Chinas. In the evening Mr. Kinsley spoke on the subject of the "Probable World's Shortage of Wheat," and read an extract from the press on this matter.

DROUGHT LESSONS.—Mr. Kinsley then read a paper under this heading. One point emphasized by the drought, he said, was the necessity for every farmer having a side line or two to provide an income when the wheat crop had failed. Whatever the side line was, energy and initiative must be behind it. In times of stress, he said, farmers were too ready to seek aid from financiers, which often resulted in

disaster, whereas good management and economy in times of plenty would in many instances enable them to tide over bad seasons. He urged members to conserve fodder. Cocky chaff should be saved, but where the complete harvester was used and the cocky chaff lost, but cost of labor saved, this money should be set aside as a reserve fund for the purchase of hay. Fodder could also be conserved by taking off portion of the crop with the binder and passing it through the header. This would leave good, clean, sheaved straw, which could be stacked. The natural grasses, too, should be given more attention. By peg-tooth harrowing and top-dressing with lime in wet weather, and subsequently brush harrowing, they could be much improved. The grasses should be cut with a grass mower or scythe, and made into ensilage. He was of the opinion that many varieties of wheat being grown in this district were unsuitable. All late varieties should be dispensed with, and more attention paid to the early and drought-resisting wheats. A lengthy discussion followed. Mr. Roberts agreed with Mr. Kinsley in his remarks on the conservation of fodder in the form of ensilage, and Mr. Riddle emphasized the value of storing cocky chaff. Mr. Giles would keep a stack or two of straw in future. Mr. Murray favored Federation wheat, but it was necessary to occasionally procure new seed to keep this variety true to type. He supported the idea of trying new varieties to ascertain the most suitable for this district.

**COORABIE** (Average annual rainfall 11in. to 12in.).

October 31st.—Present: 14 members and six visitors.

**FODDERS.**—Mr. E. J. Stretton read a paper. He urged members to experiment with different fodders to find the most suitable for this district. He had recently been in communication with a grower in New South Wales, and that gentleman had supplied him with a list of various fodders (some drought-resisting), giving their yielding capacities, and quoting prices of same. He submitted this list to members, and advised them all to try one or two of the varieties. The value of a real good fodder was inestimable in times of drought. In the discussion which followed the reading of the paper, Mr. Roberts recommended the growing of a small acreage of rye. He had had good results this season. He believed that the spineless cactus would prove a valuable fodder in this district during dry seasons. Mr. F. Gurney had tried tree lucerne, but without success.

**MANGALO** (Average annual rainfall, 14in. to 15in.).

October 3rd.—Present: eight members and one visitor.

**THE FARMER'S DIARY.**—A paper under this heading was contributed by Mr. H. S. Mackley. Experimental work, &c., he said, would not be of much value unless careful records were kept, therefore every farmer should keep a diary, and daily note therein particulars of the work carried out. The rainfall, general weather conditions, and any other items of interest should also be noted. This enabled the farmer to make comparisons of different methods of working, of the effect of different climatic conditions, &c., and also to determine whether late or early working of the land was best for his particular district. Particulars with regard to stock should also be noted. The diary would enable the man on the land to review his work for the past years, and thus benefit by his experience.

#### MITCHELL.

October 31st.—Present: seven members and two visitors.

**MIXED FARMING.**—A paper on this subject was contributed by Mr. W. Sampson. He did not think mixed farming was practicable until the land had been well cleared and worked. On light land carrying white mallee he would roll about September, and burn at the end of the summer. He would then crop early with wheat, and burn when the crop was off. This method would destroy two crops of shoots without any cutting. The next season oats (either Algerian or Calcutta Cape) should be put in. This provided a good straw to burn off the shoots a third time. After this burn the cultivator should be used as soon as possible. It would then be found that after the early rains there would be an abundance of green feed. The next season it would be advisable to bare fallow, and follow this with another wheat crop. Following the wheat crop he would leave the land open for grazing, and procure a few sheep. It was unwise to stock too heavily. As the land became free of mallee the flocks of sheep could be increased, and later on cattle could be procured. After

grazing he would sow wheat, and then fallow again. Every second or third crop should be either oats or barley. Barley was splendid grain for pig-raising. Seasons such as this, he said, demonstrated that it was wise to have more than one source of income, and not to depend on wheat alone. Members agreed with the opinions of the writer.

PENONG (Average annual rainfall, 11.93in.).

October 12th.—Present: nine members and four visitors.

THE ECONOMY OF EXACTNESS.—Under this title Mr. O. J. Murphy read a paper, in which he said:—"So many problems confront the settler on new land that mistakes are bound to be made unless forethought and care are exercised. The settler, in his haste to get land ready for cropping, is apt to trust to guesswork, and in later days regrets many times his mistake. Errors of this sort are apparent—even to the casual observer—on many of our West Coast farms. Fences have been set out in odd directions, resulting in irregularly-shaped paddocks. The house is perhaps in a corner of the block. There are enough problems to contend with without struggling against the disadvantages of a badly-placed working base, irregularly shaped paddocks, crooked fences, or ill-built sheds. The farmer, in planning out paddocks, should keep in mind two chief points, the shape which can most easily be worked by his implements, and which will give maximum area for minimum fencing. A creek or water run will sometimes determine the direction of divisional fences, but in the main the direction of the fences will be determined by the direction of the boundaries. The square paddock is the ideal one. It gives maximum area for minimum fencing, and is easily worked. Triangles should be avoided if possible. The plough must turn many times to cover a small area. This means extra strain on the horses, and if stumps are numerous the risk of straining a big plough on the turn is great. The triangle cannot be drilled without overlapping. Some ground will be drilled perhaps three times—at least twice. There is loss of time, loss of seed, and undue risk of damaging implements. If the boundaries of a block run in such directions that square or rectangular paddocks are not practicable, paddocks should have opposite sides parallel. Square or rectangular paddocks may be set out by using the chain measure alone. To set out a right angle from, say, the boundary fence, at a given point, measure from the point along the boundary a distance of 40 links. Hold one end of the chain at the given point, and 80 links of the chain at the 40-link point; if the chain be taken up at 30 links and pulled tight to form a triangle with the 40 links of the boundary as base, then the apex of the triangle will be on the line perpendicular to the fence. The same method can be used to set out the rectangular base of a shed. The accuracy of the work in the latter case may be tested by measuring the diagonals of the rectangle. They should be equal. Time spent in making accurate measurements is time well spent. The loss of time which inaccurate measurement or guesswork are sure to entail in the long run is many times greater than that which is spent in obtaining precision in the first place. It would pay a settler handsomely to obtain the services of a surveyor rather than make his paddocks ill-shaped. Accurate planning saves not only time, but fencing material. Care should be taken to erect posts in a straight line. Accuracy in minor points in ploughing, drilling, stump-picking, &c., pays well for the trouble involved. One disc of a 15-disc drill overlapped each round, means that one acre in 15 is sown with double the required amount of seed. A greater mistake is to miss space between the rounds. There is a direct loss of ground, and the weeds have an additional chance to make headway against the crop. It is a poor policy to drill land which has not been cleared of loose stumps. Apart from the trouble of stopping frequently or jumping from the footboard to throw the bigger stumps aside, there is always a certain amount of seed wasted when the small stumps drag in the discs. The seed is blocked, or else sown on the surface of the ground, and not covered. Loose stumps are a frequent cause of breakages on the drill. It is not unusual to see a ton of loose stumps per acre after ploughing. In conclusion the writer advises the keeping of records of farm work. A written record of the rainfall, areas sown each year, rate of seed and super. per acre, and harvest results is much safer than the memory, and pays well for the little time involved." An interesting discussion followed, in which members generally indorsed the opinions of the writer of the paper.

## PENONG (Average annual rainfall, 11.93in.).

November 4th.—Present: six members.

HAY-MAKING.—Mr. W. A. Roberts read a short paper on this subject. The varieties of wheat he favored were Indian Runner, Bobs, Marshall's No. 3, and King's Early. If to be fed long the hay should be cut just as the grain had formed; but if to be chaffed, it should be left for a week or 10 days later. He preferred to use the binder for cutting. Upright stooks of about 30 to 40 sheaves were the best. When building the stack, a foundation of solid timber should be used. A shed large enough to hold sufficient hay for the season's requirements would be very useful. Mr. J. Oats preferred to stook as soon as possible. The stooks should not be too big. He would build a shed large enough to hold sufficient hay for his own requirements.

## YADNARIE (Average annual rainfall, 14.09in.).

October 31st.—Present: 15 members and five visitors.

THE AGRICULTURAL BUREAU.—Mr. J. W. Darby read a paper dealing with the work and benefits of the Agricultural Bureau. Experimental work, he said, carried on by different Branches was the means of helping to raise the standard and improve the methods of farming throughout their respective districts. He mentioned also the educational value of reading and discussing papers at meetings, and emphasized the value of homestead meetings. Branches would do well to avail themselves of the assistance of the Departmental Experts. He considered that every member of the Bureau should read *The Journal of Agriculture*, from which much information could be obtained. A discussion followed, in which the Chairman (Mr. J. H. Pearce), the Hon. Secretary (Mr. J. H. Kruger), and Messrs. J. J. Deer, A. Spriggs, W. L. Brown, F. W. Dreckow, B. B. Crosby, and J. B. Kolb agreed with the paper.

BUTLER, November 17th.—Members were of the opinion that experimental work should be carried on in this district. Messrs. Parker and Jericho stated that fowls, well attended to, gave very good returns, while Mr. Phillis said that from 200 head of poultry he had had a return of £12 10s. only for 12 months.

GREEN PATCH, October 12th.—The meeting was attended by the Director of Agriculture (Prof. A. J. Perkins) and the Secretary of the Advisory Board (Mr. G. G. Nicholls), both of whom addressed the members. Mr. Gore read his report of the Annual Congress.

GOODE.—The meeting was held at the homestead of Mr. J. Whitelaw, and members found much to interest them on this member's well-kept farm. In the evening the subject of "Co-operation amongst farmers" was discussed, two extracts on the subject from the *Journal* being read. It was decided to again bring up this matter for discussion in July next.

PENONG.—Mr. W. Sanders contributed a paper dealing with the method he adopted in the treatment of colic, sand, and other troubles in horses. Members discussed the subject, and mentioned various remedies which had been tried.

## EASTERN DISTRICT.

## (EAST OF MOUNT LOFTY RANGES.)

## CLANFIELD (Average annual rainfall, 16in. to 17in.).

November 24th.—Present: eight members and three visitors.

FARMING MALLEE LAND.—Mr. H. R. Hayward dealt with this subject in a paper. By reason of the expenses incurred in the purchase of machinery, vehicles, horses, harness, &c., it was necessary that the farmer should start with plenty of capital, in order to tide over the first few seasons should they be adverse. In this district the mallee shoots and stumps were a big drawback, and anything in the nature of an effective shoot scorching would be welcomed. For a number of years, he said, the prices realised for farm produce had not been high. He favored co-operation among men on the land. He detailed the effect on the community at large of a failure of crops.

## CLAYPAN BORE (Average annual rainfall, 16in. to 17in.).

November 2nd.—Present: six members.

CONSERVATION OF FODDER.—Mr. D. P. McCormack read a paper on this subject. He recommended constructing a mouseproof bin of galvanized iron, and storing oats in this. It was unwise to stack oats in the bags. Stubble should be sown with oats, barley, or some other fodder. This year he had sown 100 acres of stubble with barley and oats, at the rate of ½ bush. of seed with 60lbs. of super. The feed obtained from this was equal to a saving of 8s. per acre for hay, which it would otherwise have been necessary to consume. It was advisable to cut oats while a little on the green side, and put them through the header, thereby ensuring a supply of good straw, and the grain in addition.

## COOMANDOOK (Average annual rainfall, 18.01in.).

October 31st.—Present: 21 members.

POULTRY FARMING.—Papers on this subject were read by Messrs C. Driscoll and F. Ballard. Owing to the shortage of green feed, &c., Mr. Driscoll said, it was wise for farmers to cull out and market hens that were not now laying, or that were over two years of age, together with all male birds not required for breeding. Half a dozen of the best pullets should be selected for breeding, and a good cockerel secured for mating with these. If egg production were the objective the White Leghorn was the only breed which need be given serious attention, but if the farmer contemplated keeping general purpose poultry, he had a wider range of choice. Personally he considered the most suitable the Black and White Orpingtons, Silver or White Wyandottes, Barred or White Rocks, and Rhode Island Reds. This policy of selection, carried out annually, would very considerably raise the quality of the fowls on the farm. He also dealt with the subjects of breeding and feeding. Mr. Ballard urged farmers to purchase a pen of good birds to form a good foundation to the flock. He favored the Andalusians, and for heavy breeds the Buff Orpington and Barred Rock. This district was very suitable for turkeys, he thought. Some members did not think White Leghorns suitable for the farmer.

## GERANIUM (Average annual rainfall, 16in. to 17in.).

October 31st.—Present: 16 members.

MISTAKES AND FAILURES.—Mr. Pannell read a paper under this heading. Many had failed to acquire some technical education, he said, and this was at the root of a number of failures. Every farmer should have a fair idea of the underlying principles governing the cultivation of the soil. Members discussed the subject at some length.

Mr. Norton thought a share plough cutting a 6-in. furrow, better than one cutting a furrow 7in. or 8in. It was a mistake to use second-grade super., he said. Mr. Lithgow preferred a heavy plough, cutting an 8in. furrow.

## GLENCOPE.

November 18th.—Present: —.

FALLOWING.—Mr. Colbert read a paper on fallowing. Land to be fallowed, he said, should be cultivated after harvest so that the weeds would germinate and a clean crop would result. Fallowing should be carried out in July and August, as early working enabled the soil to conserve moisture from the winter rains. He would fallow light sandy soil to a depth of 3in., and the loamy flats to 4in. After ploughing, the land should lie for three or four weeks to become sweetened, and then be harrowed down level. In September it should be cultivated, and after every rain the harrows should be used. In sandy soil he would plough in the stubble to discourage drift. It was a mistake to work the land while dry. New land should be fallowed the second year after clearing. A discussion followed.

## HALIDON.

November 4th.—Present: 12 members.

HAYMAKING.—Mr. D. C. Chambers read a paper on haymaking. For the hay crop he would sow equal quantities of Dart's Imperial wheat and Algerian oats in about the middle of April. The oats should be cut two or three days prior to ripening, and the wheat just after the bloom had fallen. This generally would mean cutting about the beginning of November. He preferred to use the binder. The hay should be stooked behind the binder in small stooks, and could be carted in one or two weeks, according to the weather. If

cut with the clipper, horse raked, and forked into small cocks, it could be carted the next day. New land in this district in a good season should yield about three-quarter ton per acre. Mr. Harris preferred a 5ft. binder for land where there were stumps. A tall crop should be allowed to get ripper than a shorter one before cutting; more grain for the larger bulk of straw would then be produced. Hay which got wet in the stook should be turned. Mr. Weston preferred big stooks, as the hay was apt to become dry and bleached in the small ones. Mr. Braithwaite would mix the wheat and hay in the stack. Mr. Russell considered Dart's Imperial too liable to rust to be grown for hay. Mr. Clark drew attention to the investigations made at the Roseworthy College, which showed that hay should be cut when the grain was in the milky stage, and shortly before it reached the doughy stage. If allowed to become over ripe before cutting it rapidly lost weight.

### McNAMARA BORE.

November 1st.—Present: eight members.

**POULTRY BREEDING.**—A paper on this subject was read by Mr. W. W. Hargreaves. After having chosen a strain, he said, the breeder should endeavor to keep it up to standard by culling out all weakly or poor birds. Fowls that succumbed to disease should be burnt. Over-crowding must be avoided. A scratching shed should be provided. It was important that the birds should always have access to fresh water, which should be kept in a cool sheltered spot. The fowl-houses should be warm and free from draughts. Only the best layers should be bred from. The remainder of the pullets should not have a male bird running with them, as infertile eggs were the best for market. Eggs should be collected each day. In discussing the paper Mr. Sanders stated that he preferred the heavy breeds for the farm. Although they did not lay quite so many eggs as the light breeds they brought better prices as table poultry. Mr. W. W. Paterson would only keep sufficient fowls to supply the wants of the farm. The prices offered for eggs did not warrant the keeping of large flocks. Mr. Sanders disagreed. He considered it paid better to feed wheat to fowls and pigs than to sell it at 3s. or 3s. 3d. per bushel.

### MINDARIE (formerly Cressy).

November 3rd.—Present: 23 members and two visitors.

**PIGS.**—The subject of management of pigs was dealt with in a paper by Mr. Johnston. He dealt with the origin and distribution of this animal, and the paper continued:—“If swine were given their proper place in Australia they would be found as profitable as in older countries. The first thing for us to decide is the breed most suitable for our climate, and most profitable to keep. I find the White Yorkshires and Berkshires the best all-round pigs for the farm, and of the two I prefer the Berkshire; for lean meat and shapely hams they cannot be excelled. They are also quick growers. A Berkshire at eight or nine months will often turn the scale at 150lbs. To be successful only the best animals should be allowed to breed. The fecundity of swine leaves no excuse for breeding mongrels that have to be hunted down with a rifle and dogs when wanted. A well-bred boar is sufficient for six or eight sows. There is no class of farm stock with which the well-bred or inferior animal means such a large difference between profit and loss. Therefore the breeder should always be most careful in the selection of his breeding stock. A breeding sow should have good feed, but if allowed to get too fat she will have a tendency to have small litters, and a fat sow does not remain prolific for long; this is of importance, as an old sow is the best mother. In my experience the best age to start breeding is about 10 months old for a sow, and from 12 to 18 months old for a boar. It is possible for a sow to have three litters a year, but I think two the safer plan. Gestation continues for three months and three weeks and three days; it may vary a few days according to the age and construction of the animal. A sow will probably take the boar four days after farrowing, but it is better to wait until after the young pigs are weaned. The young pigs should be castrated while they are on the milk, as it affects them the least then; at any time, however, it is not a dangerous operation. The chief care is to see that no flies get at the wound. About six weeks old is the usual time

to wean them, but care must be taken not to check their growth. Plenty of soft food and green feed, if available, should be given. I have seen pigs reared on rape alone, and topped off for market with a little grain. The two best grain feeds for pigs are peas and barley, and the barley, I feel sure, would grow in this district. Pigs in confinement often suffer for want of water, therefore never mind how sloppy their food is, always give them plenty of clean water to drink. They should always have plenty of charcoal handy, as they are very subject to worms and other stomach complaints. Always keep the sty clean. In conclusion, I consider that pigs properly kept are one of the best-paying propositions a farmer can undertake."

#### MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

October 31st.—Present: 18 members.

SCRUB LAND.—Mr. H. E. Kuchel read a paper. Scrub should be rolled in September for preference, or October, he said, and burning effected at the end of February or March, at the time of the full moon, and when a hot wind was blowing from the north. In the case of an early season, the land should be ploughed before the ashes blew away, but in a late season it should be fallowed after the cleared land had been dealt with. The soil should be well harrowed, and have the roots picked off. Light land should be left as rough as possible, and not harrowed. Seven horses could be worked in a four-furrow plough, which would be found most suitable. Cross-ploughing would pull out a number of stumps. New land should only be cropped twice, and then left out for three or four years for grass. The best time to burn stubble was with the full moon in March, at the time of a hot wind from the north.

#### PARRAKIE (Average annual rainfall 16in. to 17in.).

October 31st.—Present: nine members.

RABBIT DESTRUCTION.—Mr. Gravestocks contributed a paper. Owing to the sandy and undulating nature of this district, he said, it would not be wise to wire-net the holdings. He recommended filling in the burrows with dry sand, and banking them well up, and setting traps on the buck heaps to catch any that might be outside. The traps or soil should not be touched with the bare hands, and paper should be used to cover the traps. The unoccupied land made it very difficult to cope with the pest. In discussing the subject Mr. Jose stated that he had tried various methods, but as fast as he rid his farm of rabbits others from adjoining lands came in. He considered the use of the poison cart in summer time the most effective means of destruction. He had noticed that if the burrows were filled in the rabbits that were left outside burrowed and released those that were shut in. Mr. Parkinson had used bisulphide of carbon with good results. Mr. M. J. Cooney (Hon. Secretary) recommended ramming bags about 6ft. to 8ft. into the burrow and then filling in.

#### PARILLA (Average annual rainfall, 16in. to 17in.).

November 26th.—Present: 15 members.

SEEDING OPERATIONS.—A short paper under this heading was read by Mr. J. Tee. In preparing the land, he said, much depended on the nature of the soil and the season. Fallow land in this district should be worked well before seeding. He favored the roller. This implement pulverised the land, and packed it well, thus enabling it to conserve moisture. Land cropped last seeding time was almost the same as fallow on account of the little nutriment that had been taken from it by the season's poor crops, and should therefore not be worked too deeply next season. He would roll before drilling, and then harrow after the drill. This would ensure a good tilth and a good seed bed, but should next season prove to be a wet one, little working would be required. He would sow about 40lbs. wheat or 90lbs. oats with 50lbs. super. to the acre on stiff land, or 40lbs. of wheat or oats with 45lbs. super. per acre on sandy land that was cropped last year. A lengthy discussion followed. Messrs. J. Roachock and J. Northey agreed with the quantities of wheat, &c., set down in the paper, and Mr. Roachock would commence seeding at about the middle of March. Mr. J. Northey considered rolling would to a certain extent prevent "takeall." Mr. A. Camens would use a little more seed than the

quantity mentioned in the paper. Mr. J. J. Foale would use 60lbs. seed with 40lbs. to 50lbs. super. per acre next seeding, as there would be practically no self-sown. He did not consider the roller of much use in stumpy country. Mr. Shannon would cultivate well, drill and harrow, and sow not less than 50lbs. of early wheat. Land heavily dressed with super. last seeding would not require much super. next seeding. Mr. C. S. Foale favored the roller on well-cleared land, and would sow 1bush. of wheat to  $\frac{1}{2}$ cwt. of super. Mr. R. Rush would use not less than 1bush. of seed. Mr. A. J. Stevens would roll where possible, and harrow afterwards. A good deal depended on the variety as to the quantity of wheat sown. Mr. C. Moyle would not use much super. where the crops had been very poor last year, but where the crops had started well, the full quantity of super. would be necessary with next year's seeding. He had had good results with thin sowing. Mr. Johnson did not think rolling necessary in this district, but would use the harrows. He favored thin sowing for this year, and would sow about 40lbs. of seed wheat to the acre. Mr. G. Gregory considered that when the wheat was not graded it was necessary to sow not less than  $\frac{3}{4}$ bush. to the acre.

#### RAMCO.

November 30th.—Present: eight members and one visitor.

Mr. Odgers gave an address on fruitgrowing in Wirrabara Forest, and illustrated his remarks with lantern slides. He contrasted the soil and rainfall of that district with those of the river districts. The splendid setting of fruit in Wirrabara, he said, was due to the inoculation carried out by the bees. Since bee-keeping had been carried on in the district better crops had been gathered.

BOOKPURNONG EAST, November 28th.—Mr. Phillis stated that on account of the late crops and the distance from the market it would be unprofitable to cut hay in this district. Mr. H. Shulze would cut any crops that were high enough for hay. Mr. Mayfield stated that prices for hay in this district were only about 12s. above Adelaide prices. He favored Triumph, Cumberland, and Comeback for hay wheats.

COONALPYN, December 4th.—Mr. D. F. Laurie (Poultry Expert) attended the meeting and gave a demonstration and lecture.

MANTUNG, November 5th.—Extracts from the "Journal" on "Stack Building and Thatching" were read by Mr. W. Stewart, and discussed by members.

MANTUNG, December 3rd.—Members discussed the prospects of the coming season, and debated the advisableness of sowing a larger area than usual.

WILKAWATT, November 7th.—Reports were given by members carrying on experimental work. Mr. A. Neville stated that wheat sown with high-grade super had a nice green, broad leaf, while the plant grown with the low-grade manure was sickly-looking and had very fine leaves. Mr. D. F. Bowman had sown plots with different quality phosphates, but up to the present no difference could be observed in these plots. High grade super. was unanimously favored by members.

### SOUTH AND HILLS DISTRICT.

FOREST RANGE (Average annual rainfall, 35in. to 36in.).

October 29th.—Present: seven members.

COOL STORAGE OF APPLES BY GROWERS.—Mr. E. Rowley contributed a paper on this subject. He considered that the co-operative cool storage of apples would be to the mutual benefit of all growers concerned. He mentioned that during the picking season the packers secured a good proportion of the best keeping varieties and placed them in the Government cool stores. At that time of the year the prices were generally low. Having a few thousand cases of apples in store the middleman was thus in a position to greatly influence the trade for the remainder of the year, and practically determine the price that the grower received for his late varieties. He advised growers to form unions in the different fruitgrowing centres. Each union or branch would conduct its own business, except that which it was deemed advisable to have conducted by a committee representing all branches. There should be a uniform system of packing, grading, &c., and the fruit should

be placed in the Government cool storage by the growers, where it would be accessible to any prospective buyers. By thus cutting out the middleman, he said, fruit would reach the consumer at a lower price and the growers themselves would also greatly benefit. A discussion followed the reading of the paper. Mr. F. Green mentioned that the Victorian and Sydney growers stored their apples in Sydney. The fruit was thus ready to catch the prices immediately there was a rise. He advised the growers of this State to co-operate and follow their example. Messrs. Schultze, A. Green, W. McLaren, and E. Green also took part in the discussion.

#### INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

November 25th.—Present: 14 members.

**CULTIVATION OF PEAS.**—This subject was dealt with in the following paper by Mr. T. G. Rose:—"Land intended for peas should be ploughed early in the season, thus giving plenty of time to prepare the seed bed. I prefer drilling to broadcasting, as then the seed and manure are more evenly sown; and at the same time they are well covered. This is a consideration where rabbits and birds are numerous. The best time for sowing in this district is in July or early in August. If sown too early there is danger of trouble with frosts, and if sown too late there is the chance of troublesome hot winds. Almost any land is suitable for pea-growing if well worked and well manured. The variety most favored is the Dun, or the small white, as these run easily through the drill. They should be sown at the rate of about 2bush. per acre, with 1cwt. of either guano super. or bone super., the latter giving the better results in wet seasons. Less manure may be used in heavy soils. It is a good plan to roll the peas as soon as they are sown. This crop is valuable on new ground as it adds nitrogen to the soil. Many farmers are substituting a pea crop for the bare fallow in their rotation system. The most effective and the quickest way of harvesting peas is to rake them into rows with the ordinary hay rake, after which they should be put into small heaps ready for carting, which should be done before the peas become too ripe. The cheapest way for the small farmer is to roll the peas with an ordinary land roller, then put them through the winnower. There is no crop better than peas for the average farmer to grow for fattening sheep, lambs, and pigs. There are several different ways of feeding. Some prefer to harvest the peas, then put them out into troughs; others stack and feed out as required, but the most economical way to handle the crop is to buy forward store sheep, and turn them into the crop. The stock should have access to plenty of good water. Sheep thus fed produce first-class mutton, and will always bring a good price in the market. I know of one instance where a farmer had three acres of peas on which 55 forward lambs were put, and in a few weeks they were sold as extra prime. After the 55 lambs were fattened he put another small lot on the same three acres, and these also sold well." A lengthy discussion followed. Mr. H. J. Jagger (Chairman) stated that he had turned sheep on to a crop of peas in the winter, and found that they would not eat it while green. Mr. M. J. Meyer had had the same experience. Members favored the horse rake for gathering the pea crop—the few left on the ground could be fed to sheep or pigs.

#### KANMANTOO (Average annual rainfall, 17.90in.).

October 3rd.—Present: nine members.

**HARVESTING.**—Mr. W. C. Mills read a paper on this subject. Before commencing to harvest, he said, the farmer must consider what he will require in the way of seed and fodder. Portion of the crop should be taken off with the binder, and then thrashed. The grain could thus be obtained, and the straw conserved for fodder. It was advisable to procure the services of the most competent laborers obtainable. The market should be closely watched, for it might be more profitable to dispose of the harvest in the form of beef, mutton, or pork. Crops sown for hay might be found more profitable if left for grain, or vice versa, according to the season. At harvest time machinery should be in good order, and the teams in good heart. If the crop contained much wild oats it should be cut before these oats lost their feed value, even if the wheat were slightly green. However, if the percentage of oats were small, it would be more profitable to wait for the wheat to reach its best hay stage. If the land had not been well cleared the binder could not be worked lower than 6in. from the ground. This meant a loss of straw.

Hay should be stooked soon after it had been cut if it were to be left for some time before stacking, but if to be carted within a short time it should be left in loose rows, where it could dry more quickly. Wet hay should be stooked immediately; if left lying on the ground it soon lost its value. If the crop were to be stripped and labor were dear, it would be best to either use the harvester or reaper-thresher, but these machines must be worked by competent men to obtain best results. He preferred machines with plenty of sieve room. Vehicles and machinery should be kept in the shade as much as possible. Special care should be taken when harvesting any experimental plots, the different yields should be weighed, and the results carefully noted.

#### MOUNT COMPASS.

October 31st.—Present: eight members.

**IRRIGATION.**—An address on this subject was given by Mr. F. Slater. In dry seasons, he said, it was necessary to have some irrigation system to grow summer vegetables. The growth of late crops of cabbages, &c. could be extended by the use of sprinklers, which would also be a check on most pests. Planting out should be done during showery conditions, which could be obtained by using sprinklers. After years of experience with flooding he was convinced that in this district it did more harm than good. His plant for sprinkling consisted of a 1 h.p. petrol engine, driving a 1in. centrifugal pump, operating four sprinklers. The outfit was mounted on a hand barrow frame, and, after disconnecting the hoses, could be moved along the drains by two men. The whole cost was about £40, and it required about 1gall. of petrol every eight hours. A pressure tank system to do the same work would cost about £300. A discussion followed. Mr. Peters had been successful this season with the flooding system, but considered his land was more suited to this method than any other of the adjoining holdings. Messrs. Hutton and W. Cocks (Hon. Secretary) also took part.

#### STRATHALBYN (Average annual rainfall, 19.28in.).

November 3rd.—Present: 28 members.

**CO-OPERATIVE PURCHASE OF IMPLEMENTS &C.**—It was decided that each Branch in the electoral division of Alexandra be asked to send two delegates to confer at Strathalbyn with the object of formulating a scheme to provide for purchasing implements, &c., on the co-operative principle.

**POTATOES.**—Mr. H. Meyers read a paper on this subject. After dealing historically with the potato, he said:—"For early crops, planted in July or August, it is necessary to plant on the higher ground, fairly well-drained, and with an easterly aspect. But for summer crops, planted in December, the lower and damper land sheltered from the hot winds is best. In the case of the former it is very necessary to fallow the land as deep as possible during the summer, and then, after the first rains, plough it again to a depth of 8in. or 9in, leave in that state until two weeks before the time of planting, and then drill in 6cwt. to 8cwt. of potato manure to the acre. Practical experience has proved that to drill the manure in is more profitable than to sow it in rows with the potatoes, besides being much easier. If manure is put on the seed potato it burns the plant to a certain extent, especially cut seed, and thus the plant is weakened; and the roots remain cramped. On the other hand, if the manure is drilled, and then ploughed in with potatoes, the roots will spread all over the land in search of manure, and there is no danger of the seed suffering from the effects of the chemical content of the fertiliser. When planting it is advisable to plough about 6in. deep, but only plant the seed about 4in. down the furrow, as potatoes do not grow so well if they have a long way to come through the ground in the cold weather. From 27in. to 30in. is the usual distance between the rows, with about 14in. between each potato. Too much care cannot be taken over the selection of seed. It is useless to go to trouble to prepare the land carefully and well, and then plant inferior seed. My experience is that for the July-August crops potatoes dug in March will produce the best results. It is commonly known that Pinkeyes and Bismarcks are the best for the early crop, as they withstand the wet and cold weather much better than any other varieties, and will also recover from the effects of frost far better. Never plant seed from a poor crop. Always select big potatoes, and when cutting seed for planting throw out all those with shoots that look at all delicate; a good, strong, vigorous shoot is desirable. Run over the ground with light harrows just as the plant is coming through the ground; choose a nice

sunny day if possible, as all weeds will then be killed. After the potatoes have grown enough to define the rows, go through them with the cultivator set about 4in. deep. In about four weeks' time go over them again with the cultivator, but only very lightly, just to move the surface of the soil to not let a crust form, as one of the great secrets to successful potato-growing is to keep the soil open. This helps to retain the moisture, and aerate the soil. It is a great mistake to cultivate deeply, as some of the roots are very near the surface, and are easily broken. Potatoes should be left to properly mature before digging, the tops then die off, and the skins become firm on the potatoes. If dug before they are matured they do not keep so well, nor are they so good for market. On land for December planting I would grow a crop of field peas, planted after the first rains, ploughed in in September, and left to rot until November. I would then work the land up until it is as fine as possible; drill in 5cwt. of manure, and plant the potatoes about Christmas time, or the beginning of the New Year. Snowflakes or Carmens are the best for summer planting. They take a long time to mature, but grow rapidly after the early rains. To keep potatoes so that they will remain firm and a good light colour, choose a well-drained place in the garden, stack them in a gable-shaped heap, and put sufficient thatch on them to keep the rain out; then put earth on the thatch, but not too much, and dig a drain around the stack.

CHERRY GARDENS, December 1st.—After the formal business had been conducted and this being the last meeting for the year, members adjourned to a hall where the annual social was held. About 60 persons were present, among the visitors being the Hon. T. Pascoe (Minister of Agriculture), Mr. W. L. Summers (Secretary to Minister), Mr. G. G. Nicholls (Secretary Advisory Board), Mr. G. C. Savage (manager Blackwood Government Orchard), Messrs. C. Spencer and T. B. Brooks, of the Clarendon Branch, and Messrs. C. Morgan and W. Coates, of the Ironbank Branch.

HARTLEY, November 5th.—HOMESTEAD MEETING.—Members gathered at the homestead of Mr. B. Wundersitz, and were much interested in the general arrangement of the farm, &c. The experimental plots being conducted by Mr. Wundersitz were the centre of considerable interest.

MOUNT BARKER, December 2nd.—Mr. H. H. Corbin, B.Sc., gave a very interesting address on the characteristics of some of our forest trees. The address was illustrated by the means of lantern slides, and was much appreciated. A discussion followed.

## SOUTH-EAST DISTRICT.

MILLICENT (Average annual rainfall, 29.25in.).

November.—Present: five members.

STOCK AND CROPS.—Mr. J. B. Mitchell read a paper. Land in the South-East, he said, at its present high price, should be made to produce to its utmost capacity without deteriorating the soil. It was a mistake to crop the same land with cereals year after year, and it was not profitable to take off a crop and then leave the land to produce any chance crop of grass, or self-sown crop. Stock-raising for export should be gone in for. This would mean the growing of fodder crops. He had experimented with Dunn oats in this district, but the dry months had badly affected them. Cape barley had been tried, and had produced prolific growth. Good feed was ready fully six weeks before the natural grasses were worth much. He would burn off stubble early and then work with either a light plough or a cultivator, and drill in early with a good percentage of manure. The fodder should not be allowed to go to seed. He would stock the paddocks as heavily as possible without underfeeding. This would enrich the soil. He instanced a case of a man who had a crop of mustard near his shearing shed. He fed this off with sheep, and the next year he harvested a heavy crop of wheat from the land. He would plough in thistles growing in stubble paddocks, while they were in their green state. Thistles were also a good emergency feed. They should be cut, raked into heaps, and given time to moisten, when stock would readily eat them. He considered that the land on the Millicent flats could produce more

if properly worked. He favored cropping one year, and feeding off the next, as was practised in England. By this means the land was constantly being enriched. Oats and barley did well in this district, and rye made splendid feed if not allowed to mature. Kale and rape were not suitable for these parts. A discussion followed. Mr. Bowering stated that thistles were splendid feed for stock. Mr. Hart mentioned that where these plants were very thick it would pay to cut them for ensilage. Mr. Nitschke mentioned the different climatic conditions of England and this colony, and that there were no hot winds in England like those which swept over the Millicent flats, but Mr. Mitchell did not think that these hot winds did much damage to oats or barley. Mr. Hart stated that the local black soil would not produce barley or mustard. Mr. Fensom contended that where wheat followed an oat crop it always proved satisfactory.

#### NARACOORTE (Average annual rainfall, 22.60in.).

October 10th.—Present: 16 members.

**HORSES FOR FARM WORK.**—This subject was dealt with in a paper by Mr. W. E. Rogers. He preferred the medium draught for this district, where the soil generally was of a light character. Either a Clydesdale or Suffolk Punch stallion, mated with suitable mares, would produce first-class horses for farm work. Heavy-legged horses were at a disadvantage working on sticky land, but commanded a better price. He did not think that medium draughts consumed any less feed than heavy draughts. The lighter animal was more active and a faster walker than the heavy draught, and this was a big consideration. He considered that the Percheron crossed with the Clydesdale or any other good draught strain, would produce a suitable farm horse. In the discussion Mr. Loller agreed with most of the views of the writer. A little blood introduced into the draught class was a good thing, it meant good action and clean legs. He preferred a nuggety horse with good bone and action, and favored the Suffolk Punch stallion. He would only breed from the best available stock, which should also be good tempered. Mr. Bray and Mr. Feuerherdt also favored the Suffolk Punch stallion, and the last-named gentleman stated that good-tempered animals did not always produce good-tempered stock. Mr. Holmes preferred light draughts for this district. Mr. S. H. Schinckel (the chairman) favored the medium draught, as did also Mr. W. H. Smith, and this gentleman had a liking for the Percheron.

**ROLLING GROWING CROPS.**—Members discussed the desirableness of rolling growing crops, oats in particular. Mr. W. H. Smith thought it better to use the barrows than the roller. Mr. Loller had secured best results this year by going over the crop with a roller with the harrows attached.

**EXHIBITS.**—Mr. W. H. Smith exhibited samples of wheat and oats grown on his farm. The oats were taken from a paddock of 45 acres sown on April 17th; and the wheat from a paddock of 18 acres, sown on April 18. The wheat was Federation, about 3ft. high, and the oats (Algerian) about 3ft. high, both samples showing heads. He tabled the specimens as proof of the value of putting in crops early. Both promised a good yield. He had fed the oats off lightly with sheep. Mr. Loller was a strong advocate of early sowing of crops, and believed in getting them in in March or April. The best crops grown by Mr. Bray in this district had been sown in the middle of May. He had some good crops sown in June, but crops sown earlier had not turned out well. The chairman said that to the east of Naracoorte early sowing was the best, but in the west late-sown crops did better. The chairman showed specimens of Succession cabbages and Sydney Early Market cauliflowers he had grown. Both were fine varieties, and did well in the district. He had not used a great deal of water in growing them.

**KEITH, November 7th.**—Mr. Morcom initiated a discussion on co-operation among farmers, by means of which, he said, they would be able to dispose of their produce more profitably and also to purchase their requisites more cheaply. Members generally favored the principle.

**TINTINARA, November 28th.**—Mr. C. P. Hodge contributed a paper dealing with the advantages of systematically conducted experimental work on the farm. He urged the Branch to take steps in this direction, and formulated a scheme which he considered suitable to the local conditions.

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

### STOCK INQUIRIES.

Replies Supplied by Mr. F. E. Place, B.V.Sc., M.R.C.V.S.,  
Veterinary Lecturer.

"D.L.," Terowie, asks treatment for four-year-old draught horse suffering from strangles.

Reply.—Rub throat with hot lard or butter; steam head with few drops eucalyptus. Put teaspoonful sulphate of quinine on tongue with little Stockholm tar twice daily. On recovery give tablespoon sulphur once a day for a week.

"W.H.L." asks treatment for cow, which nine days after calving became paralysed in hindquarters.

Reply.—The paralysis of cow is due to inflammation of womb and ovaries. Treatment—15 drops of tr. nux vomica once a day and 15 drops tr. pulsatilla twice a day for a week or so.

"W.N.," Coomandook, has some sheep which are gradually becoming blind through film spreading over surface of eye; there is slight discharge from corners of eyes. He asks for advice.

Reply.—The trouble arises from anæmia, due to blood parasites. Feed sulphate of iron at 1 dram per day per sheep; dust dry boracic acid into eyes occasionally.

"J.A.H.," Tumby Bay, forwards some small red worms pumped from bottom of underground tank, and asks if they are injurious to stock.

Reply.—The little worms are larvæ of mosquitoes and gnats and are harmless to stock, but it is as well to strain them out through cheesecloth or similar material. The best way of getting rid of them

is to clean out the tank and wire gauze all possible openings into it. An ounce of chlorinated lime per 1,000galls. also is good purifier, and is almost tasteless in that quantity.

“R.C.,” Ironbank, asks if there is any cure for lumps in cows’ udders.

Reply.—Lumpy udders are always suspicious of tuberculosis, actinomyces, and similar affections, and the cows should be reported to the Chief Inspector of Stock, Adelaide, who would send an officer to inspect. On the other hand, there are lumpy udders which are not of this dangerous character; the inspector would advise. In the meantime hot soapsuds well rubbed in twice a day may somewhat improve matters if the lumps are the result of mastitis. A lumpy-udder cow is much better as beef than as a milk producer, from a profit point of view.

“F.C.B.,” Pinnaroo, asks treatment for mare that has floodings.

Reply.—A reliable and handy treatment for such an accident is to cut a lemon in two, and passing the hand into the womb, to squeeze the lemon juice into that organ, afterwards wringing out a sheet in as hot water as possible, and inserting it in the womb, removing it an hour or so later.

“E.F.D.,” Lameroo, inquires treatment for cow which has very sore front feet, hoofs deformed for several months, now lame in right hind leg, swelling between stifle and hip; otherwise seems in good health.

Reply.—The symptoms are those of scrofula, which may or may not be tubercular, probably not. It certainly will not pay to keep such a cow, as she is likely to be an uncertain breeder; but if treatment is desired, let her have twice daily for a month or so two table-spoons of syrup ferri phos. co.; this she will lick up from a saucer or mixed in her food. White liniment with  $\frac{1}{2}$ oz. oil of origanum added to each 5ozs. of liniment, may be applied to the feet and swelling once daily with advantage.

“J.S.L.” has horses suffering from irritation and soreness round coronets; moisture exuding from frogs is putrid. He seeks advice.

Reply.—The symptoms arise from bedding on dung, and are caused by a mange parasite, chorioptes. First wash with warm soap and water, and thoroughly dry; then daily apply one part benzine to five parts cheap oil. After the irritation has ceased apply lemon juice to the sores.

“J.S.,” Bute, inquires treatment for gelding, nine years, which suffers pain when passing urine, especially after some has passed.

Reply.—From the well-described symptoms in the letter the horse

has urinary calculi, and will probably find relief if 20 drops of tr. camphor are given three times a day for a week, mixed with a little molasses, and smeared on the teeth. The following week a teaspoonful of bicarbonate of potash should be given twice a day mixed in the feed.

"C.S.B.," Kybunga, had some calves which appeared to go mad; they galloped in circles, then fell down and died. They had been fed on separated milk.

Reply.—Acute indigestion is the trouble, and the calves should suck, not drink. Probably the trouble would cease if they had a little boiled linseed or calf meal with the milk, and a saltspoonful of bicarbonate of potash in each feed.

"H.R." writes that occasionally during last few weeks he has lost a fine fat lamb; examination showed bladder and kidneys very inflamed, and urine red. When sheep were being yarded the biggest wether lagged behind, and was killed; the bladder was full of a pink blotchy fluid; the kidney fat loose and jelly-like; the dung of all was loose, with inclination to scour.

Reply.—The symptoms of one of the so-called braxy-like diseases. The knife is the best treatment; but if noticed early bleeding at the eye vein sometimes gives good results. As stated, it is always the best lambs which succumb, as the germs only flourish when the blood is springing; therefore keep the lambs back a bit, constantly changing on to poorer pasture, if possible, and not letting them remain on a paddock more than three days at a time. The following mixture has been found of use as a preventive:—Cooper's sheep dip 1 part, common salt 8 parts, one dram or a teaspoonful of the mixture once daily to each lamb in dry feed, or in the mouth if a small flock, for a week or so.

"J.S.," Bordertown, wants information concerning mare which appeared to be in usual health one evening, but next morning was noticed to be lying down, and was swollen, and unable to rise, but took food during the day. She was shot the next day, and on examination all organs seemed healthy, except a patch of inflammation in the big gut, to which some worms were hanging.

Reply.—The worms were the ordinary big bloodworms, *sclerostomum equinum*; the part they play in such attacks has not been definitely settled, but if the microscope could have been used probably their offspring would have been found very active in certain glands, producing a blood poison, which in this case resulted first in flatulent colic during the first night, and paralysis of the bowels and hindquarters later. In a similar case a good remedy at the outset

would be half-pint of gin, 20 drops of essence of peppermint, and a little warm water. A teaspoonful of saltpetre and a tablespoonful of flowers of sulphur once a day for a week would probably help the other horses.

"F.W.C.," Waikerie, asks treatment for valuable colt, which suffers from intermittent heavy cough, worse after drinking.

Reply.—The cough is probably not dangerous, as it arises from irritation of cutting teeth, and may continue at intervals till four and a half years old. When it is very troublesome, a little Stockholm tar smeared on the teeth or tongue now and again will relieve, as will also liniment rubbed into the throat.

"A.G.," Kalangadoo, asks cause of death of sheep. They first tremble, then become paralysed, fall down, froth at mouth, and quickly die.

Reply.—The symptoms point to a parasitic invasion, known as sarcosporidiosis, which exists in various parts of the State, and can only be diagnosed by the microscope. Treatment is not much good, but if seen early bleeding at the eye vein is followed by good results sometimes. Prevention—Constantly move the sheep, not letting them remain in a paddock more than three days, though they can safely return in a week or two. Give dry feed, such as cocky chaff, containing for each sheep 1 dram each of flowers of sulphur, sulphate of iron, common salt.

"S.T.L." asks treatment for colt which has swellings under the belly; they are in patches, some as large as a saucer, and have scabs like ringworms.

Reply.—The swellings are no doubt parasitic, even if not ringworm, which is very probable. Dress once a week for three times with a little ointment, made of biniodide of mercury 1 dram vaseline 2 ozs. The swellings will increase after each dressing, but eventually dry up and disappear.

"T.," Port Germein, seeks advice concerning draught colt, which for past three or four months has had a soft swelling under the jaw.

Reply.—The dropsical swelling arises from anæmia, or poverty of blood, brought about by worms and lack of certain food constituents; he would improve quickly if lucerne were available. Give a dessertspoonful of syrup of phosphate of iron twice a day, smeared on the tongue; it is nice to taste, and he will soon be looking for it. A month's treatment should be enough.

"S.C.G." asks treatment for aged horse, which at times gallops wildly around the paddock, then paws the ground, lies down, the

eyes stare, nostrils distend, the tongue goes black, and the animal appears in very great pain; sweat runs off, and hard lumps appear under skin of forequarters. After an hour or two the attack passes off, and horse keeps well for some months.

Reply.—The symptoms are those of very acute abdominal pain, which might be caused by stones forming in the large bowel (calculi), but the prominence of the subcutaneous glands make it more probable that worms have a share in producing the pain. Gin and peppermint or chlorodyne would give relief at the time, but one day he will probably not recover from an attack, in which case a post-mortem would be of interest.

“R.B.,” Wirrabara, writes to the effect that he has had difficulty in getting rabbits to take phosphorus baits, and asks for information in regard to other poisons.

Reply.—Strychnine in pollard and sugar would do, but if there is green feed there will be the same difficulty, namely, that the rabbits will leave it alone. Raspberry jam, however, is a great attraction, either with phosphorus or strychnine, so are slices of apples, sown along a furrow, for instance. Roasting the baits would spoil the poison. Arsenic is used, but rabbits are tolerant of it. Prussic acid is too volatile to be of any use, but cyanide of potassium might be. Strychnine varies in strength, as sold commercially, and it is well to ask the chemist what quantity he would recommend; speaking generally, an ounce to four pounds is ample. In the Wirrabara district apples would probably be the cheapest and most successful bait.

“M.J.H.” asks treatment for filly, one and a half years, which is in fair condition, but gets down every night, and has to be lifted on to her feet in the morning, when she urinates freely. The loss of power is in her hindquarters, but when up she is able to walk.

Reply.—Symptoms of paralysis, connected with an invasion of blood worms, and in a young animal the chances of recovery are not too good. Some sort of slinging arrangement may be rigged to help her up, and she should receive in her food once a day two tablespoonfuls of Fowler’s solution of arsenic, and twice a day, in a little bran, a flat teaspoonful of sulphate of quinine. The treatment should be carried out for a fortnight, then the quinine only, and in the third fortnight the arsenic should be given again as well as the quinine. Should a post-mortem be made, the worms will be found not only in the bowels, but in the glands of the caul fat.

“Farmer,” Clare, had mare which was in pain after eating or drinking. She was treated for sand, but died nine days after.

symptoms first noticed. A post-mortem showed much water about the heart, the big gut packed with old food, with blood worms and sand; left lung very black.

Reply.—The original disease was impaction colic, and the worms probably then caused irritation; but the death was probably the result of drenches which went the wrong way, and set up pleurisy and septic pneumonia. Treatment in the first case should have been purgatives, such as an ounce of aloes, followed by bowel stimulants, such as 20 drops tr. nux vom., three times a day.

“E.L.P.” requires treatment for horse suffering from sore back caused by saddle; the withers have swollen and burst.

Reply.—The injury has produced fistulous withers; if the horse is of no value it will be best to shoot it; but if it is valuable, the wound must be probed and opened to the bottom of each pipe or sinus; the diseased tissue, which will be found black at the bottom, must be scraped away, the wounds thoroughly sprayed with petrol, and then daily irrigated with cold water for an hour till healed to the surface, when ordinary healing powder, such as boracic acid, may be used. The healing process will take about three months, the essential thing being to remove all dead tissue from the bottom of the wound.

“F.M.” asks treatment for filly suffering from strangles and a discharge from heels.

Reply.—Give a tablespoonful of Fowler’s solution of arsenic once a day in feed for two or three weeks. The discharge from the heels is due to the impurity of the blood. The warts on the nose will disappear if they are rubbed with castor oil one day and vinegar the next for a few times.

“P.” has several heifers which had lumps on front teats; they seemed loose, and were about the size of a pea; the teats went blind. He asks cause.

Reply.—Mammitis, probably of the contagious form; handle affected ones after the others, and take precaution to wash hands before handling another beast. Rub in hot soapsuds once or twice a day to affected quarter, and inject for three or four days half a tea-cupful of warm water, with a saltspoonful of boracic acid dissolved in it. In very obstinate cases, if relief cannot be given with a carefully sterilised teat syphon, the hidden bougie described in former replies will have to be used. The main thing to remember is the contagious nature of the disease, and to use all precautions to prevent spread.

"J.T." asks treatment for cow suffering from sore teats; the cow was very poor and weak, but calved all right; the skin, however, peeled off her teats and left them raw, and they continue to crack.

Reply.—These symptoms frequently occur under such conditions. It would be well to bathe the teats after milking with warm milk containing a teaspoonful of boracic acid to the pint, then to dry them thoroughly with a very soft, clean cloth, and paint them lightly over with collodion, or one of the similar preparations sold by chemists as new skin and under similar names, most of which are volatile solutions of celluloid. Under such treatment recovery should take place in a few weeks.

"T.H.S." has horse, eight years, with swelling behind and below near ear; other horses had strangles.

Reply.—The swelling is a strangles abscess, and it is not advisable to lance it owing to the big blood vessels in the neighborhood of the parotid gland, but if it is well fomented daily, and then a bit (the size of a nut) of blue mercurial ointment is rubbed in, the swelling will be reduced. Ten grains of iodide of arsenic put upon the tongue every other day for four times will also help towards recovery.

#### FERTILISERS.

"R.H.E.P." asks:—(1) The best way to use sulphate of iron as a fertilising pickle for wheat. (2) Can quicklime be used mixed with sand in place of superphosphate. (3) As common salt absorbs moisture, could it be used to supply seeds with moisture sufficient to carry them through dry spell.

Mr. W. J. Spafford (Superintendent of Experimental Work) replies:—The three main plant foods are phosphoric acid, potash, and nitrogen; and, together with lime, are the only substances usually necessary to supply to soils to get maximum crops. (1) Soils are rarely so deficient in iron (and then only in white sands) as to need applications of it in any form, so that sulphate of iron is hardly needed as a fertiliser, and when advocating copper sulphate as a "pickle" for cereals, it is always recommended to be careful that it is not adulterated with sulphate of iron. (2) Phosphoric acid has proved itself the plant food most necessary to supply to crops in this country, and this is usually done by applications of superphosphate with the seed. If you replace the superphosphate by a mixture of lime and sand you supply no phosphoric acid at all, and the only good done will be to sweeten the soil and to alter its mechanical condition; and this to an appreciable extent only if the dressings are comparatively heavy. (3) Common salt, when present in appreciable quantities, is harmful to plants, and, in fact, will make

soils quite sterile; according to A. D. Hall, 0.25 per cent. of common salt in the soil is the maximum for good crops in England; but good crops have been secured in drier countries containing up to 1 per cent. in their soils. Practically all soils in dry countries contain quite marked proportions of salt, so under these conditions it is never advised as an application for soils, and, indeed, is only used for special crops, as mangels, asparagus, &c., in the moister countries.

### HORTICULTURE.

“F.G.M.,” North Bore, asks:—(1) Cause of leaves of tomato plants dying from bottom of plant upward; (2) whether the soil (red sandy loam) in his district is favorable to the growth of onions; (3) what is the best manure for onions.

Mr. G. Quinn, Horticultural Instructor, replies:—(1) Leaves drying on tomato plants.—The gradual curling up of the lower leaves of your tomato plants is not necessarily an evidence of disease, and if the decay takes the leaves off in a more or less regularly ascending order the probabilities are their decline is due to natural causes. At any rate, avoid splashing the foliage with the bore water, or any other liquid, more particularly during periods of heat and sunshine. (2) Onions on sandy soil.—The red sandy loam should grow the onion well, but if no irrigation water is available the plants should be raised in beds and transplanted in April or May. Make small, sheltered beds and sow the seeds thickly during February or early March, covering them very lightly with a mixture of finely-sifted, well-rotted manure and sand, keeping the soil moist. (3) Manures for onions.—The manure most favored for onions is thoroughly decomposed farmyard manure. It must be old enough to have become fairly freed from weed seeds. For your sandy soil this would be better than commercially-compounded fertilisers, as humus is much needed as a rule in the sandy soils of hot climates. From 20 tons per acre may be used with advantage for this crop. Of the commercial fertilisers bone superphosphate, sulphate of potash, and nitrate of soda are recommended. Of the former, not less than 5cwts. per acre, of the potash 2cwts., and the soda nitrate 1cwt. The latter is given as a spring dressing when the plants are growing, the two former worked in before setting out the plants, or, if sown in the field, before drilling in the seed.

“G.W.K.” asks for information in regard to raising orange and lemon trees from seed.

Mr. Quinn replies:—“The seeds of orange and lemon trees are usually sown thickly in specially-prepared beds, about August or September. The seedlings are protected with calico or hessian

shading during very hot days and during cold nights. After about a year they are transplanted into nursery beds about 9in. apart, in rows which stand about 2ft. from each other. If set out in August or September and watered carefully, they will be big enough to bud in January or February. The buds remain dormant, however, until the following spring, when the top of the seedling stock is removed, and the growth forced from the inserted buds."

---

### IMPORTS AND EXPORTS OF PLANTS, FRUITS, ETC.

During the month of November, 1914, 607bush. of fresh fruits, 14,426bush. of bananas, 11,459 bags of potatoes, 1,159 bags of onions, 1,400pkgs. of vegetables, and 5pkgs. of plants, trees, and bulbs were examined and admitted at Adelaide and Port Adelaide, under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910. Three hundred and sixteen bushels of bananas and 291pkgs. of vegetables (over-ripe) were destroyed. Under the Federal Commerce Act, 1,159 cases of fresh fruits, 220pkgs. of dried fruits, and 129pkgs. of preserved fruits were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 56 cases lemons, 699 cases oranges, 220pkgs. of fruit (dried), 80pkgs. of preserved fruit, and 404pkgs. of cherries; for India, 49pkgs. preserved fruit. Under the Federal Quarantine Act, 955pkgs. of seeds, bulbs, plants, &c., were examined and admitted from oversea markets.

During the month of December, 1914, 574bush. of fresh fruit, 9,586bush. of bananas, 10,664 bags of potatoes, 812 bags of onions, 644pkgs. of vegetables, and 6pkgs. of plants, trees, and bulbs were examined and admitted at Adelaide and Port Adelaide, under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910; 434bush. of bananas (over-ripe) and 31pkgs. of cucumbers were destroyed. Under the Federal Commerce Act 243 cases of fresh fruits, 437pkgs. of dried fruits, and 234pkgs. of preserved fruit were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 15 cases of oranges, 140pkgs. of dried fruit, 238pkgs. of cherries; for London, 200pkgs. of honey; for India and East, 28pkgs. preserved fruit and 7pkgs. dried fruit; for South Africa, 260pkgs. preserved fruit and 290pkgs. currants. Under the Federal Commerce Act, 2,195pkgs. of seeds, plants, bulbs, &c., were examined and admitted from oversea markets.

## FODDER CROPS ON RECLAIMED LAND.

### SOME HIGH RETURNS.

The value of the asset which South Australia possesses in its reclaimed and to be reclaimed swamp lands has again been demonstrated by the growth of fodder crops on some of the areas held by the Government along the River Murray. When at the end of last winter it was apparent that there was going to be a shortage of feed for stock in the State, the Minister of Agriculture (Hon. T. Pascoe, M.L.C.) decided that the Director of Irrigation (Mr. S. McIntosh) should take the necessary steps to put under crop as much as possible of the reclaimed and irrigation areas under his control. It was originally intended that 2,500 acres should be sown, but owing to adverse circumstances this could not be accomplished. Nevertheless, by dint of strenuous exertion and the employment of a number of farmers, the comparatively large total of 1,200 acres was sown to various fodders. Of this over 900 acres are at Mypolonga, the balance being at Wall, Pompoota, and Swanport. The crops sown included 370 acres of Japanese millet (*Panicum crus-galli*), 250 acres of which are at Mypolonga, and 100 acres of barley, the remainder being lucerne, oats, sorghum, and maize. Other areas are still being sown. It was intended to water the whole of the reclaimed land by gravitation from the river sluices, but owing to the unprecedentedly low river, the water for two-thirds of the area has had to be pumped.

The growth and returns so far from all the crops has been very satisfactory, the millet especially having exceeded anticipations. The average height of the millet when fully matured is from 6ft. to 6ft. 6in., and at a conservative estimate the yield is from 4 tons to 5 tons of hay per acre. Portion of the crop is being chaffed direct from the field, so as to save the cost of stacking. It is proposed to sell the chaff at £4 10s. per ton at the stack, bags extra, or £4 15s. per ton at Mypolonga Wharf. The green millet is sold at 5s. per one-horse load, an additional 5s. being charged for each extra horse. Judging by the way it is now coming on a second cut should yield from 30cwt. to 2 tons per acre, and immediately it is taken off the same land will be sown to oats or berseem. The Irrigation Department was extremely fortunate in getting supplies of seed of the latter, as most of the other consignments for South Australia were shipped by the German steamer *Roon*, the whereabouts of which is at present somewhat of a mystery.

A few particulars of the cost of cropping the millet at Mypolonga should prove of interest, as showing the profitable nature of the crop. It was sown in September, 1914, and harvesting was begun on December 24th. The cost of cultivation worked out at 15s. per

Japanese Millet - Mypolonga.

acre; seed, 10lbs. per acre, 2s. 6d.; drilling, 3s.; irrigating by gravitation twice, 2s. per acre (at Wall, Pompoota, and Swanport, where irrigation was done by pumping, the cost was 5s. per acre); cutting, 4s. to 5s. per acre; a total of 27s. 6d. per acre, or, on a return of 4 tons to the acre, 6s. 10½d. per ton. The cost of carting to the

chaffcutter was 3s. per ton, or carting and stacking 4s., and chaffing cost 10s. per ton, the contractors finding everything but bags. The total cost, less binder twine, of the millet cut for chaff was therefore approximately 19s. 10½d. per ton, all the work being done by contract.

As regards the other crops, it may be stated from 70 acres of lucerne at Mypolonga, which was sown in September, 1913, three cuts have already been taken this season, and it is now ready for the fourth cut. It is estimated that the four cuts will represent 6 tons of dry hay or chaff per acre. On the same area 30 acres of lucerne was put in this season; this was mixed with self-sown oats, and the first cut yielded 2 tons of dry hay per acre. The lucerne chaff is being sold at £6 per ton, and large quantities of green lucerne is also being disposed of at from £4 to £5 per acre per cut. In December 90 different orders for lucerne were fulfilled. The lucerne at Mypolonga was sown on the stronger land—river frontage-land—which is more difficult to work, and the cost of putting in, including drilling, was £2 15s. per acre, in addition to which the seed cost 15s. per acre. At Pompoota and Wall the average cost of cropping lucerne and other fodders was 25s. per acre, both on the high and low swamp lands.

### CIDER-MAKING APPLES.

In his report to the Minister, dated London, November 6th, the Trade Commissioner gives the names of the varieties of apples which were awarded first prize at the Brewers' Exhibition for the best collection of cider-making apples. They are as follow :—

|                   |                    |                    |
|-------------------|--------------------|--------------------|
| Canon Bittersweet | Cherry Norman      | White Norman       |
| Chisel Jersey     | Medaille D'or      | Skymes Kernel      |
| Kingston Black    | Bramtot            | Green Wilding      |
| Royal Wilding     | Cummy              | Cowans Red         |
| Strawberry Norman | Sams Crab          | White Beach        |
| Handsome Norman   | Upright Red Streak | Broadleaved Norman |
| Fertile du Eden   | Old Foxwhelp       | Eggleton Styn      |
| New Foxwhelp      | Red Norman         | Cherry Permain     |

## AGRICULTURAL STATISTICS.

### REPORT FOR 1913-14.

The complete report on last season's production prepared by the Assistant Government Statist (Mr. W. L. Johnson) and the other officers of the department has been forwarded to the Chief Secretary (Hon. J. G. Bice, M.L.C.) by the Government Statist (Mr. L. H. Sholl, C.M.G.). Much of the data has already been published, but the report also contains some interesting additional information, extracts from which appear below. The figures in parentheses refer to the season 1912-13.

#### FERTILISERS.

Not many years ago the use of artificial manures was practically unknown on farms. They are now generally used. For the last three seasons 84 per cent. of the area under crop has been treated with artificial manures such as superphosphates, bonedust, &c., to the extent of 91,607 tons in 1912 and 97,023 tons in 1913.

The following details for the season 1913-14 will be useful :—

| Division of State.     | Area Cropped. |           |                              | Quantity of Manure Used. |                   |
|------------------------|---------------|-----------|------------------------------|--------------------------|-------------------|
|                        | Total.        | Manured.  | Percentage Manured to Total. | Total.                   | Average per Acre. |
|                        | Acres.        | Acres.    | %                            | Tons.                    | Lbs.              |
| Central.....           | 1,062,047     | 884,118   | 83.25                        | 40,060                   | 101.5             |
| Lower North.....       | 818,167       | 726,625   | 88.81                        | 27,486                   | 84.7              |
| Upper North.....       | 290,950       | 183,032   | 62.91                        | 4,834                    | 59.2              |
| South-Eastern .....    | 440,287       | 375,038   | 85.18                        | 11,718                   | 70.0              |
| Western .....          | 557,223       | 490,195   | 87.97                        | 12,915                   | 59.0              |
| Outside Counties ..... | 885           | 600       | 67.80                        | 10                       | 37.3              |
| Total, 1913-14 .....   | 3,169,559     | 2,659,608 | 83.91                        | 97,023                   | 81.7              |
| Total, 1912-13 .....   | 3,062,998     | 2,588,133 | 84.50                        | 91,607                   | 79.3              |

In addition 100,435 (111,434) loads of natural (stableyard, &c.) manure were used on 15,206 (15,003) acres.

#### ACREAGE UNDER CULTIVATION.

The total area under crop, fallow, and sown grasses last season was 4,769,459 acres, an increase of 138,295 acres on the previous season. In 1883-4 the area under cultivation was 2,754,560 acres, in 1903-4 3,291,083 acres, and in 1913-14 4,769,459 acres. The area cultivated in 1913-14 shows an increase of 2,014, 899 acres, or 73 per cent. on the record of 30 years ago, and 1,478,376 acres, or 45 per cent. on that of 10 years ago.

*Area in Fallow.*—The area annually placed in fallow has substantially increased during the last five seasons. In 1909-10 it was 1,198,450 acres, whilst in 1913-14 the acreage placed in fallow for the following season was 1,569,623 acres. The area of fallow land sown last season was nearly equal to half the total area under cereals, and this proportion has been fairly maintained during the last five seasons.

*Area under Crop.*—The area actually under crop for the season was 3,169,559 (3,062,898) acres, an increase of 106,661 acres. Of the total area, 3,104,366 acres were under cereals for grain, hay, and fodder, the balance of the area being devoted to vineyards, orchards, and market gardens. The area under cereals for grain and hay in 1883-4 was 2,256,542 acres, and in 1913-14 it was 3,104,366 acres, the increase being equal to 38 per cent. In comparison with 10 years ago the area under wheat, barley, oats, and hay shows an increase of 911,083 acres, or 41 per cent.

In proportion to population, South Australia has the largest area under crops of any of the States, being nearly one-fourth of the whole. The total area cropped in the Commonwealth for the season 1913-14 aggregated 14,682,953 (13,838,049) acres, giving an average of 3·06 (2·98) acres per head of population. The proportion for each of the States was—South Australia, 7·31 (7·12) acres per head; New South Wales, 2·52 (2·10) acres per head; Victoria, 3·15 (2·95) acres per head; Queensland, 1·15 (1·05) acres per head; Western Australia, 4·90 (3·92) acres per head; and Tasmania, 1·35 (1·45) acres per head.

#### CEREAL, HAY, AND FODDER CROPS.

*Wheat.*—To show the importance of the wheat harvest to the State it may be mentioned that the mean annual value for the last five seasons of the wheaten grain and hay crop was £5,296,789, the value of the 1913-14 crop on the average prices to date being £4,190,579. As intimately associated with wheat culture the fact should be remembered that the capital invested in machinery and implements owned by farmers was in 1913 assessed at £2,961,334; and, further, that the prosperous condition of the farming industry is directly reflected in the flourishing condition of many of the secondary industries of the State, notably the agricultural implement and machine works, which for 1913 numbered 53, all employing four or more hands, the total hands being 1,092, who received in wages £114,086, and turned out work to the value of £287,456.

In view of the exceptionally low average rainfall of 17·20in. over the agricultural area of the State for the year 1913, the production of cereals and hay for the season under review is most satisfactory. It should be specially noted that the wheat crop has averaged 21,652,903bush., or 10·27bush. per acre for each of the last five seasons, the Lower North Division alone having averaged each season in the same period 7,765,053bush., or 13·42bush. per acre.

## ESTIMATED VALUATION OF ALL CROPS.

| Kind of Crop.                     | Total Value. |            | Percentage of Value to the Total. |          |
|-----------------------------------|--------------|------------|-----------------------------------|----------|
|                                   | 1912-13.     | 1913-14.   | 1912-13.                          | 1913-14. |
|                                   | £            | £          | %                                 | %        |
| Cereals (all kinds) .....         | 4,253,926    | 3,367,851  | 53·80                             | 54·32    |
| Hay " .....                       | 2,180,036    | 1,571,944  | 27·57                             | 25·35    |

| Straw .....                       | 56,221       | 40,693     | ·71                               | ·66      |
| Root crops .....                  | 264,325      | 155,108    | 3·34                              | 2·50     |
| Vineyards .....                   | 544,232      | 431,580    | 6·88                              | 6·90     |
| Market gardens .....              | 106,736      | 121,224    | 1·35                              | 1·96     |
| Orchards.....                     | 391,433      | 384,478    | 4·95                              | 6·20     |
| All other crops .....             | 38,209       | 47,862     | ·48                               | ·77      |
| Total .....                       | £7,908,285   | £6,200,247 | 100·00                            | 100·00   |
| Decrease .....                    | —            | £1,708,038 | —                                 | —        |

## VALUE OF PASTORAL EXPORTS.

The value of the exports of pastoral products—animals (living), meat (frozen, &c.), skins and hides, tallow, wool, &c.—to countries beyond the Commonwealth States for the last five years is as follows :—1909, £2,401,304 ; 1910, £2,720,783 ; 1911, £2,571,660 ; 1912, £2,685,321 ; and 1913, £2,518,394. The following table shows the number of sheep, the number of pounds of wool exported, the declared value and rate per pound at port of shipment, and also the London price of average Adelaide greasy wool for the last 10 years. The rainfall for each season is also given. Exports for the last four years are to overseas countries only.

## S.A. Wool Exported (In Grease and Washed).

## DAIRYING.

Notwithstanding the exceptionally dry year the dairying industry shows an increase in the production of cheese and only moderate decreases in the production of butter, bacon, and ham. At the end of the year 76,293 (79,325) cows were reported in milk, a decrease of 3,032 ; and 31,586 (35,409) to be dry, a decrease of 3,823 ; the total number of dairy cows being 107,879, or

6,855 less than the previous year. The production on farms and in factories for 1913 was as follows :—*Butter*.—8,036,274 (9,394,557) lbs. ; decrease, 358,283lbs. *Cheese*.—2,216,985 (1,958,027) lbs. ; increase, 258,958lbs. *Bacon and Ham*.—3,265,773 (3,771,064) lbs. ; decrease, 505,291lbs. Of the total quantity of butter made 3,621,200 (3,585,269) lbs. were made on the farms, and 4,415,074 (4,809,288) lbs. in factories.

*Butter, Bacon, and Cheese Factories*.—There are 12 (12) bacon and 48 (48) butter and cheese factories in the State, the latter being described as 26 (25) butter, 12 (12) butter and cheese, and 10 (11) cheese factories. These employ 270 (278) hands—261 (268) males and 9 (10) females. They possess machinery estimated to be worth £34,189 (£32,326), the power of the engines (full capacity) being 655 (686) h.p. In these factories 8,811,155 (9,918,766) gallons of milk were used in making 4,415,074 (4,809,288) lbs. of butter and 2,162,779 (1,962,307) gallons for making 2,214,865 (1,954,770) lbs. of cheese. In addition, bacon and hams were cured to the extent of 2,520,035 (2,672,256) pounds.

*Butter, Bacon, and Cheese Making on Farms*.—It is not generally known that nearly all the separating is done on farms. As a matter of fact only about 25 per cent. of the total of 10,973,934 (11,881,073) gallons of milk used in factories were treated there, the balance having been separated on farms and the cream sent to the factories : 10,919 (11,426) hands—1,356 (1,489) males and 9,563 (9,937) females—are reported to be engaged on farms in connection with dairying. Of course, it is recognised that the greater number of these hands are also engaged in many other industries as well. The value of plant and machinery used on farms is estimated to be worth £105,401 (£103,659) ; 12,214 (11,781) separators are in use ; 9,777,240 (9,457,408) gallons of milk were used in making 3,621,200 (3,585,269) lbs. of butter, and 2,200 (3,450) gallons in making 2,120 (3,257) lbs. of cheese. In addition, bacon and hams were cured to the extent of 745,738 (1,098,808) lbs.

#### MISCELLANEOUS.

*Bee-farming*.—The keeping of bees is generally carried on in conjunction with other pursuits. With a suitable climate and natural flora it is surprising that the industry does not rapidly increase. Information respecting this pursuit was first obtained for the year 1890, when it was found that 1,115,779 pounds were gathered. The year 1900 was very favorable, the returns for that year showing 26,700 hives and a production of 1,708,133lbs. of honey. The production for the last five years has been as follows :—1909, 812,487lbs. ; 1910, 996,376lbs. ; 1911, 760,094lbs. ; 1912, 1,446,364lbs. ; 1913, 876,395lbs. The returns for the year 1913 show 19,808 (24,274) productive hives and 7,909 (2,954) unproductive—a total of 27,717, in comparison with 27,228 of the previous year ; 876,395 (1,446,364) lbs. of honey and 11,607 (18,054) lbs. of beeswax were gathered.

*Poultry*.—It is estimated that the poultry and egg production of the State for the year was worth £569,254 (£541,489). The returns show that there are 1,440,385 (1,381,880) fowls, 55,659 (53,340) ducks, 18,245 (19,356) geese, and 49,066 (43,920) turkeys in the State. In many parts of the State foxes are reported to have been very destructive to poultry during the past year.

*Ensilage*.—There are 49 pit and 5 stack silos on farms, with a total capacity of 121,792 cub. ft., and the quantity of ensilage made was 778 (2,200) tons, valued at £860 (£2,039).

*Wattle Bark*.—South Australian wattle bark holds a high place in the market for tanning purposes. The quantity of bark stripped was 5,277 tons, compared with 6,892 tons of the previous year. The exports during each of the last five years were as follows :—1909, 5,189 tons ; 1910, 1,631 tons ; 1911, 551 tons ; 1912, 1,098 tons ; 1913, 262 tons—£54,432 ; £15,208 ; £5,089 ; £10,817 ; £2,628. The smallness of the shipments for 1910 onwards is due to the exclusion of the interstate trade, the figures given representing direct oversea trade only. Apart from this, large shipments are made to the other States for their own use and for transhipment to oversea countries.

### BLUE VITRIOL FOR WHEAT DRESSING.

Farmers who buy blue vitriol for the purpose of dressing their seed wheat must be careful to obtain the material of a pure character. According to the reports of the principal chemist of the Government Laboratory, says the *Mark Lane Express*, blue vitriol or copper sulphate is frequently adulterated with iron sulphate. Samples taken of parcels sold by chemists and others for "wheat dressing" were examined with a view of ascertaining their purity, and hence efficiency for the proposed purpose. Some of the samples, although labelled "copper sulphate," or "blue vitriol," contained large quantities—50 per cent. to 70 per cent.—of iron sulphate ; and other samples described under various fancy names, or "wheat dressing," contained only about 20 per cent. of the active ingredient, copper sulphate. When purchasing blue vitriol (sulphate of copper), care should be taken to demand a product of 98 per cent. purity, while the article offered as agricultural sulphate of copper should be carefully avoided. The usual adulterant is sulphate of iron, which is much cheaper. An easy test, according to a note in the *Journal of the Board of Agriculture*, for the presence of iron in sulphate of copper is to dissolve a little in water and add ammonia, constantly stirring until a deep blue liquid is formed. Any quantity of brown flocks floating about in this blue liquid indicates the presence of so much iron that the sulphate of copper should be subjected to a proper analysis before use.

#### MANURE PLOTS—*continued.*

##### 6. CITRATE SOLUBLE PHOSPHATES.

In the experience of some countries citrate soluble phosphates, of the basic slag type, are quite as effective as the water soluble superphosphates; indeed, even the untreated ground phosphatic rock is said to give satisfactory results in some countries. Neither in the matter of basic slag, nor *a fortiori* in that of untreated ground rock, has this hitherto been the experience of South Australia. The reason of this would appear to be the shortness of our rainfall supply and the intensity of surface evaporation, leading to comparatively dry soil conditions over the greater portion of the year. Oxidation phenomena and bacterial action appear, too, to be very energetic, and lead to the rapid destruction of organic matter, which, under different conditions of climate, tends to accumulate in the soil and later on to re-act on the less soluble forms of phosphates with which it is brought into contact.

In Table XXX. below will be found an analysis of results secured in the Permanent Experiment Field Plots, between 1906 and 1913, with basic slag. These results are shown in comparison with two adjoining plots, one left unmanured and the other dressed regularly with 2cwts. of superphosphate. In all cases we are dealing here with twin plots, alternately under wheat and bare fallow.

| Means          | 1  | 8  | 15 | 1  | 18 | 80  | 1  | 14 | 39  | — 11·28 | 1 | 14 | 67  | — 10·63 |

We gather from the above table that dressings of both 2cwts. and 3cwts. of basic slag remained in the average inferior both in the matter of grain and of hay to a dressing of 2cwts. of superphosphate.

The grain difference was represented by 2bush. 48lbs., of a value of 9s. 10d., or 13·21 per cent. for the 2cwt. dressing of basic slag, and by 1bush. 35lbs. of a value of 4s. 11d., or 6·68 per cent. for the 3cwt. dressing of the same manure.

The hay difference (hay equal total produce x 0·82) was represented by 5cwts. 36lbs. of a value of 9s. 4d., or 11·8 per cent. for the 2cwt. dressing of basic slag, and 5cwts. 2lbs., of a value of 8s. 9d., or 10·63 per cent. for the 3cwt. dressing of the same manure.

At the same time it should be noted that plots dressed with basic slag were invariably superior to the unmanured plots. In the average results there was an improvement of 26·75 per cent. in grain yields, and of 22·09 per cent. in hay yields in favor of the 2cwt. plots, and of 36·28 per cent. in grain yields, and 22·98 per cent. in hay yields in favor of the 3cwt. plots.

In the general conclusion, therefore, at Roseworthy we have found basic slag active as a wheat manure, but not the equal of superphosphate. Curiously enough, the seasons in which the favorable influence of basic slag was most pronounced were 1909 and 1910, the two wettest seasons of the series, whereas it was least effective in the typically dry years. These facts would appear to confirm the view that whilst basic slag is a valuable manure, it is not generally sufficiently soluble for dry climates.

Finally, it should be borne in mind that whilst in Europe basic slag is in every sense a cheaper manure than superphosphate, this is not the case here. Both manures are worth locally about £4 5s. a ton; and whilst local superphosphate usually tests 36 per cent. to 38 per cent. of tricalcic phosphate rendered soluble, local basic slag tests about 35 per cent. of total calcium phosphate, only 15 parts of which are citrate soluble and the balance acid soluble. Analytically, therefore, both from the point of view of richness in total phosphoric acid, and from that of the general solubility of the phosphate, ordinary superphosphate shows to much better advantage than basic slag. This may be taken to confirm independently field results of ordinary practice.

#### 7. NITROGENOUS MANURES.

Of all manures used, the most costly are undoubtedly those that are purely nitrogenous. This will be clear when we consider respectively the local "unit values" of nitrogen, phosphoric acid, and potash. With nitrate of soda at £14 a ton, the unit value of nitrogen is about 18s. 8d.; in 36/38 superphosphate at £4 5s. a ton the unit value of phosphoric acid is 5s., whilst the unit value of potash is 5s. 10d. in good commercial sulphate of potash at £14 a ton. In face, therefore, of this great costliness of nitrogenous manures, it is only very clear demonstration of their practical value that is ever likely to lead to any very extensive local use of these manures. It cannot be argued in this instance that there is any popular prejudice against manures to be overcome amongst farmers. Phosphatic manures broke down this prejudice years ago, and it may be said to-day that farmers are prepared to take up any manure that can be shown to promise a reasonably certain margin of profit. And the fact that little or no nitrogenous manures are as yet availed of in local farming practice, might lead to the opinion that they have been found wanting in South Australia. At the same time it should not be overlooked that much of the early work of Lawes and Gilbert at Rothamsted demonstrated very clearly the paramount importance of nitrogenous manures in English farming. According to their results it would appear as if in England at all events, wheat yields rose and fell with the importance of the dressing of nitrogenous manure applied. Hence, if it can be shown that these manures are without local value, we must assume that climate governs very largely the relative effectiveness of nitrogenous manures.

In the plots of the Permanent Experiment Field attention has been given to nitrogenous manures in the three forms in which they are commercially available, viz. :—(1) Nitrates. (2) Salts of ammonia. (3) Organic nitrogen (farmyard manure).

#### NITRATES.

Nitrates were represented in these plots from the outset by two pairs of plots, in which the land was alternately under wheat and bare fallow. In the first pair of plots (Nos. 30 and 31) the wheat has always been drilled in with 2cwts. of 36/38 superphosphate to the acre, and immediately afterwards

broadcasted over with 1cwt. of nitrate of soda. In the second pair of plots (Nos. 32 and 33) the wheat has been drilled in with the same quantity of superphosphate, and later on in August, *i.e.*, in spring, broadcasted over with 1cwt. of nitrate of soda. This arrangement was adopted because of the great solubility of all nitrates, and their general tendency to leach out of the soil under the influence of heavy rain. Indeed, in countries in which nitrates are common as a manure it is always customary to apply them in the form of a spring top-dressing. There is, however, good reason to believe that conditions of growth are quite different in South Australia. Growth is practically continuous throughout the winter months, and it may be assumed that plants will stand quite as much in need of nitrates in the earlier periods of their development as later on. Hence it was decided to test the action of nitrates both as a dressing applied at seed time, and as one applied in the spring.

Returns from nine seasons dealing with these plots, together with those from neighboring plots (Nos. 28 and 29) dressed with 2cwts. of superphosphate only for purposes of comparison, are shown in Table XXXI.

We shall notice in the first instance that, taking into consideration the mean results of nine seasons, nitrate of soda applied at the rate of 1cwt. to the acre, whether at seed time or later on in spring, has led to an appreciable improvement in both grain and hay fields.

With nitrate of soda, top-dressed immediately after seed time, the mean improvement in the grain yield is represented by 2bush. 51lbs. per acre, or 13.66 per cent, and having a value of 10s. at 3s. 6d. a bushel.

For the same plots the mean improvement in total produce is represented by 4cwts. 4lbs., or 10.25 per cent., and corresponding to 4cwts. 103lbs. of hay, having a value of 8s. 7d. at 35s. a ton.

With nitrate of soda applied as a spring dressing the mean improvement in the grain yield is represented by 2bush. 39lbs., or 12.24 per cent., and having a value of 9s. 3d. at 3s. 6d. a bushel.

For the same plots the mean improvement in total produce is represented by 3cwts. 90lbs., or 9.66 per cent., and corresponding to 4cwts. 72lbs. of hay, having a value of 8s. 1d. at 35s. a ton.

Now, the local value of 1cwt. of nitrate of soda having latterly been 14s., it will be seen that in no case have the improvements in yields, connected with its use, been profit bearing. It need hardly be argued that a manure which leads to improved yields, but at a loss to the farmer, will not be adopted in general practice.

For the moment, however, we must content ourselves with registering the fact that the use of nitrates, under South Australian conditions, certainly leads to improvements in both grain and hay crops, and that the profitableness of these increased yields is dependent on an increase in the average prices of produce, grain or hay, or on a decrease in the cost of nitrate of soda.

Secondly, we may notice that the percentage increase over and above that attributable to the action of superphosphate alone, and connected with the use of nitrate of soda, has varied very considerably from season to season. It has varied from slight minus quantities to over 80 per cent. On the whole it may be stated that the action of nitrate of soda has been most marked in the years of good rainfall, and that in years of drought its action is hardly appreciable.

Thirdly, the mean returns of nine seasons show a tendency to favor the practice of applying the nitrate of soda at seed time rather than in spring. The difference between these figures are, however, very slight, and vary in their direction from year to year. Normal and dry years appear to favor the earlier application of nitrates, whilst years with wet springs give better results from a spring top-dressing. These results are quite comprehensible in the light of what has already been said on this subject.

Fourthly, we must notice that, contrary to what is said to be the case in Europe, nitrate of soda stimulates grain production quite as much, if not more so, than flag and culm growth.

Thus whilst the mean percentage increase in grain, attributable to the use of 1cwt. of nitrate of soda applied at seed time is represented by 13.66 per cent., that of the total produce is represented only by 10.25 per cent.; or, if we subtract the weight of the grain from that of the total produce, we find increase in culm and flag weight to be represented by a little over 9 per cent. An inspection of figures relating to results from nitrate of soda applied in spring leads to similar conclusions. We gather, therefore, that under our conditions of climate nitrate of soda applied in the quantities indicated does not stimulate unduly the wheat crop in the direction of stem and leaf growth.

Curiously enough, too, the use of nitrates has not had the effect of impairing the quality of the grain, to the extent that the latter may be gauged by the bushel weight. The mean bushel weights for the nine seasons are as follows:—Wheat without manure, 62½lbs.; wheat with superphosphate only, 62½lbs.; wheat with superphosphate and nitrate of soda at seed time, 63lbs.; wheat with superphosphate and nitrate of soda in spring, 62½lbs.

#### LIGHTER DRESSINGS OF NITRATE OF SODA.

A 1cwt. dressing of nitrate of soda having yielded increases that were not profit bearing, plots were established in which lighter dressings were tested. Below, in Table XXXII., will be found the results of a ¼cwt. dressing of nitrate of soda in conjunction with 2cwts. of superphosphate (plots 60 and 61), comparatively with the nearest 2cwt. superphosphate plots (Nos. 58 and 59).

These results show very clearly that  $\frac{1}{2}$ cwt. of nitrate of soda is too small a dressing appreciably to affect the yields of grain or lay in a wheat crop under our conditions of growth.

In 1912 a new series of plots was set going in which the dressing of nitrate of soda was raised to  $\frac{1}{2}$ cwt. (Nos. 62 and 63). The results of two seasons are indicated below in Table XXXIII., comparatively with the nearest 2cwt. superphosphate plots (Nos. 58 and 59).

TABLE XXXIII.—*Showing results from Wheat dressed with  $\frac{1}{2}$ cwt. of Nitrate of Soda and 2cwts. of Superphosphate, comparatively with Wheat dressed with 2cwts. of Superphosphate alone, 1912-1913.*

| Means..... | 13                           | 50   | 15                                                            | 43   | 1                            | 2  | 65 | 1                                                                | 5  | 5  |

We are not justified in drawing general conclusions from no more than two seasons' results, particularly when they were rather abnormal, as was the case both in 1912 and 1913. We shall, therefore, content ourselves with observing that a dressing of  $\frac{1}{2}$ cwt. of nitrate of soda did influence favorably the yields of both grain and total produce, and that the increases noted just about paid for the cost of the manure used.

#### RAISING THE DRESSING OF SUPERPHOSPHATE.

Finally, it might be argued that relatively to 1cwt. of nitrate of soda, a dressing of 2cwts. of superphosphate is too small for the plants to take full advantage of the former. We know that superphosphate stimulates grain and straw growth of our crops very considerably; we have seen, too, that when combined with the latter, nitrate of soda exercises an equally favorable influence. It is possible that this influence may be even more pronounced, and even become profit bearing at average local prices, if the dressing of superphosphate be raised. Accordingly in 1912 a new series of plots (Nos. 64 and 65) were started, in which the wheat crop receives 3cwts. of superphosphate and 1cwt. of nitrate of soda. The results of the two seasons are shown below, comparatively with those of the nearest 2cwt. superphosphate plot.

TABLE XXXIV.—*Showing results from Wheat dressed with 3cwts. of Superphosphate and 1cwt. of Nitrate of Soda, comparatively with Wheat dressed with 2cwts. of Superphosphate alone, 1912-1913.*

| 1912 ..... | 19                          | 5    | 25                                                  | 14   | 1                           | 8  | 45 | 1                                                   | 17 | 41 |
| 1913 ..... | 8                           | 35   | 8                                                   | 39   | 0                           | 16 | 85 | 0                                                   | 17 | 81 |
| Means..... | 13                          | 50   | 16                                                  | 57   | 1                           | 2  | 65 | 1                                                   | 7  | 61 |

Again we must point out that the data from two abnormal seasons do not justify the drawing up of definite conclusions. We shall merely note increases from the use of the manure, increases, however, that do not meet the cost of the manure used.

#### SALTS OF AMMONIUM.

Sulphate of ammonia is frequently availed of in Europe as a manure in lieu of nitrate of soda. In this connection it presents the advantage of not leaching out of the ground as readily as the nitrate; not because it is less soluble in water than the latter, but because the soil elements—chiefly clay and humus—appear to hold it very firmly. Hence leaching does not begin to take effect until the soil bacteria have transformed the ammonium salt into available nitrates. Bacterial action may be said to be suspended in the winter months of the colder countries, hence it is judged safe to apply sulphate of ammonia as a winter dressing, whilst it is found necessary to apply nitrate of soda in spring. Under our conditions, which imply both plant growth and bacterial activity in the winter months, sulphate of ammonia should be applied as a winter top-dressing immediately following seeding operations. The sulphate of ammonia plots were first set going in the Permanent Experiment Field in 1911 (Nos. 45 and 46). Data concerning them are shown below in Table XXXV. :—

| 1911 ..... | 17                          | 32   | 17                                                      | 50   | 1                           | 13 | 12 | 1                                                       | 14 | 9  |
| 1912 ..... | 19                          | 5    | 27                                                      | 17   | 1                           | 8  | 45 | 2                                                       | 0  | 99 |
| 1913 ..... | 8                           | 35   | 6                                                       | 7    | 0                           | 16 | 85 | 0                                                       | 12 | 23 |
| Means..... | 15                          | 4    | 17                                                      | 5    | 1                           | 6  | 5  | 1                                                       | 9  | 6  |

Here again the mean increases attributable to the influence of sulphate of ammonia just about pay for the cost of the manure used. It should be added, however, that the results of three seasons are hardly sufficient to justify the formulating of definite conclusions on the subject.

#### ORGANIC NITROGEN.

The value of farmyard manure as a manure for wheat has been tested in the plots of the Permanent Experiment Field since its inception in 1905. The farmyard manure has been spread over the ground before fallowing operations at the rate of 14 tons to the acre, and ploughed under in the early winter. This is the standard dressing adopted by Lawes and Gilbert at Rothamsted. It will be interesting to note the quantities of useful mineral matter brought to the soil in this dressing.

The composition of farmyard manure is, of course, very far from constant. It varies with quite a number of factors, such as the types of animals from which it is derived, their age, the character of the food supplied, the mode of handling and manufacture, &c., &c. We may, however, adopt the following figures as substantially correct for average conditions :—

|                      |                                      |
|----------------------|--------------------------------------|
| Nitrogen .....       | 0·47 per cent., or 10·53lbs. per ton |
| Phosphoric acid..... | 0·30 per cent., or 6·72lbs. “        |
| Potash .....         | 0·52 per cent., or 11·63lbs. “       |

Hence, in 14 tons of farmyard manure there would be *nitrogen*, 147·42lbs., or as much nitrogen as there is in 8cwts. 87lbs. of ordinary nitrate of soda ; *phosphoric acid*, 94·08lbs., or as much phosphoric acid as there is in about 5cwts. of 36/38 superphosphate; *potash*, 162·82lbs., or as much potash as there is in about 3cwts. of ordinary commercial sulphate of potash.

Probably, when we take into consideration the usual dressings of artificial manures, the quantity of useful mineral matter brought to the soil in 14 tons of farmyard manure will appear excessive. Nevertheless it should not be forgotten that an organic manure of this kind is not strictly comparable with the highly soluble and highly concentrated artificial manures. In the first place, however efficiently prepared, farmyard manure must be looked upon as a relatively slow acting manure, the influence of which extends over a number of years ; in other words, its mineral matter is very far from being in as available a form as that of the usual artificial manures. Nor, on the other hand, is this mineral matter in a state of high concentration, which places within easy reach of the roots of plants an abundant supply of the minerals they require.

The benefits of farmyard manure are not, however, restricted to the mineral matter which it conveys to the soil. In addition to the latter it supplies an abundance of organic matter, which favorably modifies the mechanical condition of the soil, increases its water-holding capacity, and improves

life conditions for useful soil bacteria; in other words, farmyard manure counteracts completely some of the evils of constant bare fallowing.

Data bearing on results secured from the use of 14 tons of farmyard manure since 1906, comparatively with those from wheat dressed regularly with 2cwts. of superphosphate, and from wheat wholly unmanured, are shown below in Table XXXVI. :—

It will be noted that if we take the mean returns of eight years, 14 tons of farmyard manure to the acre were inferior in their influence on a wheat crop to a dressing of 2cwts. of superphosphate. In the matter of grain, there was a difference of 2bush. 17lbs. against farmyard manure, or 10.77 per cent. In the matter of hay, a difference of 3cwts. 32lbs., or 6.9 per cent. On the whole, these differences, although quite appreciable, are not very pronounced. Moreover, a glance at the table will show that in some seasons these differences have been in favor of the plots treated with farmyard manure. Very markedly was this the case in 1909 and 1910, two comparatively wet seasons. In dry seasons, on the other hand, superphosphate has always shown very much to advantage.

If, however, we compare results from wheat dressed with farmyard manure with those from unmanured wheat, we shall have occasion to notice differences in yield much to the advantage of the farmyard manure. Thus the mean grain yields are 4bush. 20lbs. higher in the farmyard manure plots, or 30·3 per cent. and the hay yields 9cwts. 69lbs. higher, or 20·91 per cent.

There can, therefore, be no question as to the real influence of farmyard manure, under Roseworthy conditions, on the wheat crop. It is true that this influence is not as pronounced nor as satisfactory as that of superphosphate. It is, nevertheless, undeniable. Moreover, we do not wish to be understood to hold that farmyard manure can in any way replace superphosphate. We merely wish to suggest that under judicious management it may be found to round off very satisfactorily the results of phosphatic dressings. Farmyard manure is a natural by-product of every farm; it is the earliest type of manure used by tillers of the soil; its value may be said to have been consecrated by the practice of centuries in other lands; and it appears to us that steps should be taken to ascertain how it can be handled to best advantage under our own peculiar conditions. And it is from this point of view that new farmyard manure plots were started in 1912, in which the organic manure has been associated with mineral manures. Data concerning these plots are shown below in Table XXXVII. :—

TABLE XXXVII.—*Showing Comparative Results from Wheat dressed with Farmyard Manure alone, with Farmyard and Artificial Manures, and with Superphosphate alone, 1912-13.*

The above results, it is true, refer to two seasons only, and abnormal seasons at that; we cannot, therefore, pretend to formulate from them any very definite conclusions. We shall, therefore, confine ourselves to the remark

that whilst, in these two seasons, the results from superphosphate alone were decidedly superior to those from farmyard manure alone, the combination of farmyard manure with artificial manures gave, both in the matter of grain and in that of hay, yields that were decidedly superior to those from superphosphate alone. Whether these increased yields are likely to be profit bearing or not, we are not as yet in a position to state; on the results that are available they would not appear to be so. We anticipate, however, that in years to come, with the return of more normal seasons, these increased yields are likely to be more pronounced, and we must leave to our successors the task of discussing their financial value.

#### THE POSITION OF FARMYARD MANURE ON A FARM.

We are not wedded to the idea that farmyard manure should on every farm be applied directly to a wheat crop; very far from it. It appears to us that its most advantageous position is in the way of a dressing to forage crops adapted to the district. The wheat crop that follows the forage crop more or less closely will then reap from it all the advantages farmyard manure is able to confer upon it, and will avoid some of the disadvantages that attach to it. There is no doubt, for instance, that farmyard manure stimulates—sometimes unduly—flag and culm growth; that it is apt to encourage soft, sappy growth, and lays the crop open to blighting under the stress of unfavorable early summer weather; that it encourages weed growth, &c. If, however, the farmyard manure be applied to a forage crop, and not directly to the wheat crop, all these disadvantages are very considerably minimised; and its judicious use we confidently believe will do much towards maintaining the general fertility of our agricultural lands.

#### GENERAL CONCLUSIONS.

(27) Basic slag, whilst not altogether ineffective as a manure for wheat under Roseworthy conditions, does not equal the results secured from equal and even lighter dressings of 36/38 superphosphate.

(28) At existing rates basic slag is a more costly manure than superphosphate, and cannot therefore be recommended for the district.

(29) Basic slag shows to best advantage in wet seasons.

(30) A dressing on 1cwt. of nitrate of soda combined with 2cwts. superphosphate has, under Roseworthy conditions, the effect of increasing grain yields by 13 per cent. to 14 per cent., and hay yields by 10 per cent. to 11 per cent. over and above yields secured from superphosphates alone.

(31) At average ruling rates for grain and hay, and for nitrate of soda, these increased yields are not profit bearing.

(32) The action of nitrate of soda on the wheat crop is most pronounced in wet seasons, and has led to increases of as much as 80 per cent. in grain

production, which increase is certainly profit bearing. On the other hand, the influence of this manure is practically nil in years of drought.

(33) In wet years, and particularly on soils light in texture, we suggest that a dressing of nitrate of soda is likely to prove advantageous.

(34) Under our conditions of climate nitrate of soda should be applied fairly early in the growing season of the wheat crop. If this manure is adopted as a matter of regular practice, we suggest that it be broadcasted immediately after seeding, and harrowed in. If, on the other hand, this manure is availed of occasionally only, and when the season appears to warrant it, we would suggest that the top-dressing should be broadcasted as early as circumstances permit of. A late top-dressing would be without influence except in unusually wet springs.

(35) In our experience nitrate of soda does not encourage flag and culm growth at the expense of the grain, nor does it lead to a lower bushel weight.

(36) In the matter of weight of dressing, 1 cwt. of nitrate of soda to the acre may, perhaps, appear excessive. We have secured no appreciable results from  $\frac{1}{2}$  cwt. dressings, and would suggest  $\frac{1}{2}$  cwt. dressings as likely to meet average local requirements.

(37) Our data are as yet insufficient to pronounce on the possible value of the practice of raising the phosphatic dressing when using nitrate of soda.

(38) From somewhat limited data we infer that, under Roseworthy conditions, sulphate of ammonia is quite as effective as nitrate of soda.

(39) Farmyard manure has an appreciable influence on the yields of both grain and hay crops at Roseworthy.

(40) A dressing of 14 tons of farmyard manure to the acre does not, however, lead to yields equalling those of a dressing of 2 cwt. of superphosphate.

(41) Increased yields from the use of farmyard manure are most marked in wet seasons.

(42) On the results of data that we recognise as insufficient, we suggest that maximum yields of both grain and hay can be secured by combining farmyard manure with suitable dressings of artificial manures.

(43) In ordinary practice we recommend that farmyard manure be applied to forage crops preceding wheat, and not directly to the wheat crop.

*(To be concluded.)*

## FRUIT FOR SOLDIERS AND SAILORS.

### WORK OF VEGETABLE PRODUCTS COMMITTEE.

All who to any degree realise the deprivations from which our soldiers and sailors now engaged in the defence of the Empire suffer as compared with the rest of the community will be interested in the work of the Vegetable Products Committee. The Committee is a very influential body, and the hon. secretary (Mr. E. Jerome Dyer) in forwarding a circular giving the particulars printed below, asks that publicity should be given them in order that they might be brought under the notice of likely contributors.

The circular states—

“With the recognition and support of the Admiralty and War Office, the Vegetable Products Committee has been formed with the following objects :—

- (1) To collect and deliver fresh fruit and vegetables, jams, preserves, &c., supplied free of cost, to warships in accessible stations, army camps and depôts, hospitals and other institutions, and
- (2) To assist in the organisation of fruit and vegetable industries.

“The first and immediate purpose of the Committee, which is a purely voluntary body, is to supply our warships, the crews of which get neither fresh nor preserved fruits, except what they pay for out of their own pockets. They cannot well afford to do this, and even if they could, it is impossible while they are at sea. The value of fruit and vegetables to sailors on protracted active service is inestimable. The fitness of our men in the North Sea should be our paramount consideration. The strain and exposure which they are now undergoing, and which will be immeasurably increased during the cold, foggy weather, now close at hand, call for our deepest sympathy, and demand from us every possible effort to ameliorate the severe trials which they are bound to endure. The torpedo and submarine flotillas, and mine-sweeping trawlers will have the Committee's special attention.

“The Committee's scheme has the approval of the Admiralty and War Office, and a telegram has been received from Admiral Sir John Jellicoe, in which he says—‘Fruit would be greatly appreciated by the men, and I hope it may be possible to arrange with the Admiralty for its delivery.’

“The most ample expression of our thankfulness can never repay the deep and unpayable debt which the people of these islands owe to the Royal Navy. The peace and quiet which we now enjoy in the midst of this most terrible war is solely due to the quenchless spirit of our seamen, and to their lonely and ceaseless vigil on the danger-strewn waters of the North Sea. The officers and men of our navy should be incessantly reminded of our devotion and gratitude, and our unwavering confidence in their watchfulness and courage.

"The Vegetable Products Committee hopes that public financial support will enable it not only to make its work of notable value to the Services, but also in the organisation and development (through its country branches which are now being formed) of the fruit and vegetable industries. In this direction it expects to be able to assist the refugees in this country by utilising the services of such of them as are skilled gardeners, but in no instance will any such employment be encouraged in cases where it may result in the displacement of home labor. This will be left to the judgment of the branch committees, whose policy in this matter will be guided by local conditions. Donations to the Committee's funds should be sent to the Treasurers, Messrs. Jackson Pixley & Company, chartered accountants, 58, Coleman Street, London, E.C. All gifts of fruit, vegetables, jams, and preserved fruits should be addressed 'Vegetable Products Committee,' Salvage Warehouse, Paddington Goods Station, London. Only fruit and vegetables in first-class condition, and most carefully packed, should be sent. In every case a post card should be sent to the Committee's office address, advising the dispatch of each consignment.

"The following fruits and vegetables are required :—Fruit—Apples, pears, walnuts, and quinces. Vegetables—Potatoes, onions, carrots, beets, turnips, and parsnips. Onions are particularly recommended. Potatoes or onions may be sent in sacks, but all other vegetables (and fruits) should be packed in boxes, barrels, or crates. Green vegetables will all be accepted (separately packed) for the supply of hospitals and army camps. The name and address of the sender should be stated on the outside wrapper or on a tie-on label, of each package, together with the class and approximate quantity of each parcel's contents.

"The Committee sent its first consignment to the fleet on October 14th. By October 29th upwards of 900 large cases, barrels, &c., of gifts of fruit and vegetables had reached His Majesty's warships through the Committee's Central Distributing Depôt at Paddington. This was exclusive of several packages of vegetables, &c., to army camps and hospitals. Jams and preserved fruits (which the Committee is most anxious to collect for vessels such as submarines, &c., which have no canteen and no storage space for fresh fruit and vegetables), are being stored in the depôt until the fresh fruit supply slackens. Many country committees are being formed to make jam for supplying the fleet and hospitals later on.

"If the Committee were in a position to pay railway carriage on gifts of fruit, &c., sent to its Central Depôt, it is believed that the present supply to the fleet would be more than quadrupled. Funds are urgently invited for this purpose, and also for carrying out the Committee's general objects."

The hon. secretary's address is Alderman's House, Alderman's Walk, London, E.C.

## SAVING TIME AT SEEDING.

### SOME USEFUL TABLES.

At a meeting of the Green Patch Branch of the Agricultural Bureau the Hon. Secretary (Mr. C. J. Whillas) submitted the following paper and tables, which farmers should find of considerable interest and value in connection with their seeding operations:—

“ If seed and super. are properly distributed along the headland according to the length of the paddock and in the quantities required to be sown, much time and labor are saved. Further, such proper distribution enables the farmer to adjust his drill to a nicety to the quantity of seed he wishes to sow. Usually this distribution is mere guesswork, and pans out far from correct. By using the following tables the farmer can see at a glance, without going into intricate calculations, exactly how to put out the bags. The average table gives for the different size drills in common use, for different lengths of lands, the area in acres to one decimal point that the drill should register for the return trip over the paddock. From this table the length of the land can be ascertained if not known; or, if the drill register is out of order, the acreage drilled, arrived at for any known lengths of lands. It must be remembered that lin. of mud on the drill wheels will cause the drill to register an area about 4 per cent. less than it actually drills.

“ The seed and super. tables show in yards, to one decimal place, the distance apart to put down bags of super. and 2bush. butts of seed for most of the usual quantities put in and lengths of lands usually met with. The seed, after pickling, is generally put into 2bush. butts, which are of a handy size for emptying into the drill. Should 3bush. bags be used, they will of course require to be put down just half as far apart again as would be required with the butts for the same seeding. Should heavier dressings of super. be required than those shown in the table, the distance can be easily calculated. Take, for instance, 140lbs. per acre. This is double 70lbs., so that the distance apart would be just half the 70lbs. column. With the lands 110 chains long super. or seed would require to be placed at distances half that required for 55 chain lands.

“ The following shows how to use the tables. A farmer wishes to sow a 120-acre paddock with  $\frac{3}{4}$  bush. wheat and 80lbs. super. per acre, using a 13 x 7in. drill. He will require 120 divided by 2.6 = 42 butts of seed of 2bush. each, and 120 divided by 2.3 = 52 bags of super. If he does not know the length of the paddock he can put into the drill one bag of super. and one butt of seed, adjust the feed to what he considers will sow his requirements, then drill down to the end of the paddock and back. The drill registers  $1\frac{1}{2}$  or 1.5 acres. From the average tables it can be ascertained that the lands are 65 chains in length, and a bag of super. is required at every 7.9yds. and seed butts at every 9yds. He then puts the bags out at these distances, allowing for that which is in drill. Then he goes on drilling, and will find his requirements just at the spot where they are wanted; if not, the drill feeds need adjusting.”

## ADVISORY BOARD OF AGRICULTURE.

---

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, August 12th. The Chairman (Mr. G. R. Laffer, M.P.) presided, and there were also present the Director of Agriculture (Prof. Perkins), Principal of the Roseworthy Agricultural College (Mr. W. J. Colebatch), Chief Inspector of Stock (Mr. T. H. Williams), Col. Rowell, C.B., Messrs. J. Miller, C. E. Birks, A. M. Dawkins, and G. G. Nicholls (Secretary).

### SCALP MONEY FOR FOXES.

The Secretary reported that the suggestion (considered at a previous meeting), made by a Branch of the Bureau in the Franklin Harbor district that foxes should be proclaimed under the Wild Dogs Act, to enable the Vermin Boards to offer scalp money for them, had been referred to the Chairman of the Land Board (Mr. E. B. Jones) and the Surveyor-General (Mr. E. M. Smith), who had commented as follows:—Mr. Jones—“The extraordinary increase of foxes during the last few years is a matter of grave concern, and I consider that means should be provided for their destruction, which is likely to be achieved only by paying for scalps.” Mr. Smith—“In many districts foxes are not considered a great trouble, and owing to the vast number of rabbits which they destroy many people do not take any steps to destroy them. Foxes are ‘vermin’ under the Vermin Act, but there is no provision under the Wild Dogs Act for payment for scalps of these animals. ‘Wild Dog’ is defined by the Wild Dogs Act as ‘dingo and any cross of the native dog, and also a dog run wild’ No payment can be made under the Wild Dogs Acts for scalps of foxes unless the provisions of the Acts are altered to include them, but power is given under the Vermin Act for payment to be made for their destruction.” It was decided to forward a copy of these views to the Branch in question.

### BERRI IRRIGATION FARM.

After a brief discussion it was agreed to send on to the Minister of Agriculture, for a report, the appended communication from the Renmark Branch of the Bureau:—“That this branch, while fully recognising the value of the work being done at present at the Berri Government Experimental Farm, desires most emphatically to express its opinion that much wider scope should be given to research experiments, with a view of ascertaining fresh varieties of fruits and products suitable for growth under irrigation. This branch considers that a type orchard under river conditions is urgently needed, and that its experiments should cover as wide a field as possible. It is already recognised that some sorts of apples and pears are specially suited for the river, and it is certain that some of these do only indifferently elsewhere. Take, for example, the apple Dutch Mignon. This apple has succeeded only indifferently in some districts, whereas it has

proved a dessert apple of the highest quality in every respect under irrigation in Renmark. It is urged that this is the sort of experimental work which the Government should immediately take in hand. In view of the magnitude of the irrigation works under construction this Branch is so impressed with the great need for enlarging the field of irrigated products that it desires most respectfully to urge the earnest consideration of this matter."

#### DISTRICT CONFERENCES.

In view of the effects of the drought, it was determined to allow the annual conference of the Upper Northern Branches of the Bureau to lapse for this year. The Secretary intimated that he had written to 16 Branches on the subject. Of the six which had replied one had favored holding the fixture, and the others had opposed it. Present indications, he added, pointed to the annual conference of the Northern Branches being conducted at Crystal Brook during the last week in February. The South-Eastern bodies would meet at Mount Gambier on March 24. A suggestion from the Tarcowie Branch that papers to be read at conferences should be printed and distributed to delegates before they were read at the conference was left in the hands of the Secretary.

#### DRY BIBLE.

In reply to an inquiry as to whether many cases of dry bible had been brought under his notice lately Mr. Williams said that his attention had been called to several cases, including some in the metropolitan area. The Stock Department had constantly urged on owners of cattle the necessity for supplying their animals with salt and bone-meal. An American authority, concluded Mr. Williams, had stated that not less than 3ozs. of salt should be given to each dairy cow daily, and, in addition, a plentiful supply of cool, fresh, and pure water.

#### BERSEEM AT ROSEWORTHY.

In answer to a question by Col. Rowell whether there had been any falling off last year in the average production of berseem (Egyptian clover) at Roseworthy College, Mr. Colebatch stated that in 1912 the total quantity of greenstuff taken from 1.19 acres was 38 tons 12cwts. 56lbs., representing an average return of 32 tons 9cwts. 18lbs to the acre. In 1913 the acreage cropped was 3.201, the aggregate yield—108 tons 19cwts. 97lbs., and the average 34 tons 11lbs. to the acre. Last year, however, not only was the area cropped (2.294 acres) slightly smaller, but both the total and average returns revealed a shrinkage, the former having been 46 tons 16cwts. 94lbs., and the average 20 tons 8cwts. 43lbs.

#### NEW BRANCHES, ETC.

*Sherlock.*—Approval was given to the reorganisation of the Sherlock Branch, the following members being approved:—C. E. Mann, H. E. Turner, T. Partridge, O. Klem, H. Platten, A. G. Schneider, H. Roberts, J. P. Trezoni, H. H. Hoad, J. Chas. Genders, P. B. Hoad, A. Osborn.

*Mypolonga*.—The formation of a new Branch at Mypolonga was approved, with the undermentioned gentlemen as foundation members:—P. H. Pickering, W. E. Noles, E. J. Webster, H. H. Clarke, T. H. Pinches, H. Smelt, W. Farnham, W. H. Aust, J. McTherlie, H. F. Aust, A. G. Collas, J. Mills, H. Kleemann, E. G. Wright, F. Jury, M. Raynor, G. G. Hall.

On account of the absence of evidence of effective work, Branches at Willunga and Greenock were closed.

*New Members*.—The undermentioned gentlemen were approved as members of the following Branches:—Laura, L. Giles; North Boorowie, V. R. Hannaford; Naracoorte, T. J. Tidy; Narrung, G. Reece, J. McBeath; Blyth, W. Hutchens; Mindarie, F. W. Witt; Goode, R. G. Jolly, W. S. Stasinowsky, W. A. Stasinowsky; Tatiara, F. Satchell; Long Flat, J. W. Rawnsley; Coomandook, J. D. Kilmarlin; Mount Barker, T. F. Miell; Hartley, G. Phillips; Crystal Brook, J. Pridham; Netherton, H. B. Brumby, A. M. Fergusson; McNamara Bore, H. Kelley, R. Horsfall, F. Williams; Whyte-Yarcowie, E. Green, R. Ley; Clare, W. Martin; Milang, J. Bagley, H. W. Pavy, J. Warren; Belalie North, W. Smart; Mallala, A. Earl, F. Jenkins, R. C. East; Mount Compass, F. McKinley; Hartley, A. Hutson; Koonibba, E. E. E. Lutz, B. H. Koch, C. W. Kloeden, H. F. Kloeden; Strathalbyn, Dr. H. H. Formby, A. E. Cameron; Naracoorte, T. Douglas, H. A. W. Watson; Wilkawatt, F. Oram.

Barrage at Waikerie.

Owing to the low state of the River Murray it was found necessary by the Irrigation Department to impound water for irrigation supplies at the main pumping stations. Four dams were constructed by the Department—one at Waikerie, another at Berri, and two at Kingston; the total cost approximately was £450.

## POULTRY NOTES.

[By D. F. LAURIE, Government Poultry Expert and Lecturer.]

### ECONOMY IN FEEDING POULTRY.

The abnormal prices which have of late ruled for all the principal poultry foods have severely crippled the industry, not only in this State, but in Australia as a whole. Not since 1881 has wheat been such a price—in that year, I remember, large parcels were sold at 6s. 6d. Bran and pollard have both been as dear or dearer. In many cases farmers have had no wheat, and they and many breeders have been unable to procure wheat or other poultry foods, except at ruinous prices. In the Adelaide water district the scarcity of water has acted still more rigorously, as there are many who have no green feed. Where water is available, from wells, bores, or other sources, green food can be grown, and the cost of feeding poultry can be much reduced. Of all green foods for summer use there is none to compare with lucerne for body and succulence. Kails do remarkably well where there is room; but, acre for acre, the lucerne is the better. There are hundreds who have neglected the golden opportunity in other years of securing a good water supply by wells, bores, or proper dams. Where there is good water lucerne can be grown. For the average poultry breeder half an acre, or very much less, if properly attended to, will give a surprising quantity of poultry food. I have often pointed out that green food, in addition to cheapness of production, supplies the valuable mineral salts so essential to the welfare of poultry and other stock, and which grains and seeds generally do not supply. There has been in the past a settled prejudice against lucerne growing, and yet the wonderful growths, without irrigation, in the Roseworthy College paddocks should be an object lesson to northern farmers. With the return of good seasons every farm in the north should have a small paddock devoted to lucerne, which should be cut, cured, and eventually, in time of need, fed to poultry. Lucerne hay will, if properly cured, keep for years. At the present time the poultry at Parafield are receiving over 60 per cent. of lucerne in their morning mash. Without this abundant supply of lucerne I doubt if the station could be carried on. A small grinding mill is a great help to any poultry farmer. By having one you can purchase oats, maize, &c., and grind to a meal. From such a meal—much richer

than bran and pollard, and often cheaper—you can compound a cheap and excellent mash. If you have no green lucerne, nor lucerne hay chaff, you can procure good wheaten or oaten hay chaff cut on the green side. Pour over this chaff some boiling water, cover with a bag, and allow it to steam over night. This softens the fibres, and when mixed with bran and pollard, or ground wheat, oats, and maize, makes a cheap and effective mash—you can use this chaff to the extent of 40 to 50 per cent. of the bulk of the mash.

### DO NOT SACRIFICE YOUR POULTRY.

Even at these high food prices hens of good laying strains will give a net return, although small. Farm mongrels and unselected stock will prove unprofitable. But many people appear to be panic-stricken, and thousands of useful fowls have been sacrificed. Experience should convince one that the drought will not last for ever, and that good fat years will return, and soon. The ill-advised sacrifice of so much of our poultry stocks will mean a great shortage in production, and there is no doubt the future of the egg market will be one of high prices. When these prices arrive there will be few to benefit, as the stock has been sacrificed to such an extent. Cull out and dispose of your unprofitable stock, by all means; this should be done in good years as well as in lean years. Surplus male birds, old hens, and weedy chickens should be cleared out promptly, but good laying hens and pullets coming into profit should only be sold as a last resort. If circumstances compel you to lessen your numbers, at least endeavor to retain a small flock, from which to build up a flock later on.

### THE FUTURE OF THE INDUSTRY.

Despite the bad seasons, the war, and low prices in local markets, I say decisively that at no period in our history has the future of the poultry market looked more promising. Although stress of circumstances has compelled many to part with their stock, on all hands one hears of a determination to breed largely in the future. The extreme prices will have their day, and then return to normal. Excessive prices for cereals and mill products are not in the interest of the community as a whole. History proves this fact. One effect of the war will be to open to Australia an excellent market in England. England draws her egg and poultry supplies largely from the Continent. One effect of the war will be the destruction of most of the Continental poultry, and a big shortage will result. Even before the war there were ample indications that the gradual rise in price of eggs in England would permit us to ship to that market at a net price in advance of that paid locally. Years ago I said that local

supplies in Australia would overtake demand, and that we must ship oversea. Vested interests had temporary success in lulling the energies of our producers; but 1915 egg markets have taught a lesson I hope they will not forget.

### SICKNESS AMONG POULTRY.

Despite the efforts of the Department to urge poultry owners to exterminate poultry ticks and other parasites, it can safely be said that 90 per cent. of the losses are due to these parasites, and that the losses could be avoided. Use every endeavor to eradicate all ticks and red mites; these live in the houses, paling fences, pepper trees, &c. The scurf and feather-eating and sucking lice live on the birds. For the woodwork use kerosene, pure or mixed with fat, dirty oil refuse, &c. On application to the railway authorities, Adelaide, you can purchase very cheaply the refuse from the manufacture of the Pintsch gas, used for lighting railway carriages. This is excellent for use in infested poultry houses, fences, &c. The birds may be dipped in kerosene emulsion (10 per cent.), or in Cooper's sheep dip, phenyle, phenytas, and numerous other proprietary dips. The male birds should be caught and examined at frequent intervals. They seldom dust themselves as hens do, and they, in consequence, are badly infested, and lose condition, and may die. At any rate, they do not, when poor, fertilise many eggs.

### FARMERS AND POULTRY.

In all the States the farmers have been sacrificing their poultry. In the evidence given in Sydney before one of the Grain Boards it was stated that in December alone 20,000 laying hens had been rushed into the sale rooms. It was at the same time stated that in a few months eggs would be 3s. to 3s. 6d. a dozen in Sydney. My strong advice to all farmers is to cull out and dispose of all unprofitable poultry, and prepare for restocking with high-class utility birds. One of the functions of Parafield Poultry Station is the breeding of high-class stock for farmers. It is gratifying to note that during the year a great many members of the Agricultural Bureau Branches have secured at low prices a large number of high-class White Leghorn cockerels and breeding hens. I should like farmers to take the opportunity of securing a pen of good birds, so that during the autumn and winter they may hatch a good stock of chickens, to replace those which have been sold. The harvest next year, according to averages and past experience, should be good, and there will be plenty of food available by the time the stock are forward enough to require much food. During this month I shall be able to dispose of

the last of the season's White Leghorn cockerels, and there will also be a few cockerels of White Wyandotte, White Rock, White Orpington, and R.I. Red breeds, but no pullets. To meet the times, and to encourage our farmers and producers, the price will be very moderate and the stock first class. I can spare a hundred or so first-class second-season White Leghorn hens at drought prices. In the Pinnaroo district there are many who contemplate systematic breeding this season, and I hope to hear from them. I hope they will all remember to grade and prepare a nice block of land for lucerne near the well or bore. This will mean a great deal with poultry feeding.

### VISITS TO PARAFIELD.

Members of the Bureau, farmers, and others in the country are cordially invited to visit Parafield. One or two Bureau branches have so visited the station, and I should like to hear from others, so as to make arrangements to personally show them the work. Incubation will begin again in March, and continue until May. There are many items of interest to farmers, such as the stock, buildings, mammoth incubator, and brooder houses, the laying competition, the lucerne and other fodder plots, bore, methods of grinding poultry foods, &c. The regular visiting days are the first Wednesday and fourth Saturday in each month, but when these are not convenient to country visitors I will gladly arrange for another day.

Full Stream of Murray below Barrage at Kingston, January 10th, 1915.

D. F. LAURIE, Poultry Expert and Lecturer.

### **SEED WHEAT DISTRIBUTION.**

For many weeks past large numbers of applications for seed wheat under the Drought Relief Act have been received in the office of the Hon. the Commissioner of Crown Lands. The Grain and Fodder Board has been purchasing, through its agents, all the seed wheat offering in the country, for the purpose of supplying those whose applications are approved by the officers administering the Drought Relief Act; and also, when those requirements are met, to supply seed wheat for cash to farmers who may have been unable to purchase elsewhere.

Under the arrangements made by the Grain and Fodder Board for the distribution of this seed wheat, the services of the railway station masters and harbor masters are being availed of. Advice is sent to each successful applicant of the number of bags of wheat to be sent to him, the place from which forwarded, and the firm by whom dispatched. On taking delivery of the wheat farmers are required to give a receipt on the prescribed form.

### **MINNIPA EXPERIMENTAL FARM.**

Towards the middle of January the Minister of Agriculture, the Director of Agriculture, and the Horticultural Instructor paid a short visit to the site of the new Eyre's Peninsula Experimental Farm at Minnipa. This farm is situated in very good mallee country, and should, in the course of time, prove a good advertisement for the possibilities of this vast area of country. An approximate site for the main buildings was determined upon, and arrangements have been made for preparing the plans of a small water scheme from granite rock catchment for the farm. In the coming season very little will be done in the matter of cropping beyond growing enough hay for the requirements of the farm.

## A MODEL LIVE STOCK INSURANCE COMPANY.

According to the *Journal of the Board of Agriculture*, in 1880 a number of horseowners at Newark, in Nottinghamshire, founded an unregistered mutual insurance society on co-operative principles for the insurance of their horses. This society proved so successful that by 1898 it had accumulated a reserve fund of about £600. Some of the members then wished to divide up the fund, and in order to avoid this suicidal action it was resolved to form the society into a limited liability company. No money was paid to the members, nor were they required to pay any money for their shares in the new company. The shares were allotted to the then members of the old society in proportion to the amount each member had paid in insurance contributions during its existence.

The company, which still resembles in some respects a co-operative society, was incorporated under the Companies Acts to carry on the business of insurance of horses, cattle, sheep, pigs, and other animals against death, loss, or damage from any cause whatsoever, and to provide veterinary medical attendance on the illness of any animal insured. Power was also taken to lend money to customers and others having dealings with the company on such terms as might seem expedient. The capital was declared to be £1,000, divided into 1,000 shares of £1 each, and the liability of members was limited.

According to the balance-sheet for 1913 the company possessed assets amounting to £830, viz., cash, £222; investment, £600; loan to insurer, £8; against which the only liability was £647 due to shareholders, thus leaving a balance of profit up to date, after payment of dividend and bonus, of £183, of which £102 was classed as reserve and £81 as profit of the year. Of this amount £77 13s. has since been paid as dividend to shareholders, and the remainder carried to the reserve fund, which now amounts to £106.

The share capital consists of 647 £1 shares, all paid up. The shareholders have received a dividend of 6 per cent. in 10 of the 12 years, and of 12 per cent. last year, so that they have received an average of 6 per cent. on their share capital for the whole period. The policyholders have received a bonus in nine of the 12 years varying from 5 per cent. to 20 per cent. of the amount paid by them in premiums, so that their bonuses averaged for the whole period 11 per cent. of their premiums, and as they paid a premium of 5 5-6 per cent. on the market value of their horses, the net premium actually paid by

them, after allowing for the bonus, was 5 1-5 per cent. of the market value, in return for which they not only received two-thirds of the market value of any horse that died, but also had the benefit of veterinary attendance on any insured horse that fell ill.

The average number of horses insured was 170, and the average number of horses on which claims had to be paid was 3.9, so that the average casualty rate per annum was 2.3 per cent.; in the best year, 1913, no death occurred; and in the worst year, 1912, the casualty rate was 5 per cent. The total number of losses in the 12 years was 47, and the total amount paid on claims was £526 14s., so that the average amount paid per claim was £11 4s., and as the amount payable is two-thirds of the market value, it appears that the average market value of horses that died was about £17. The worst year of the series financially was 1911, in which, of 140 horses, six died, requiring payment by the company of £93, or an average of about £15 10s. per horse, so that the average market value of the horses that died in that year was about £23. This was the only year of the series in which the society's accounts showed a loss on the working of the year, amounting to £8 5s., and in that year neither bonus nor dividend was paid. For the whole period the amount paid on claims averaged £43 18s. per annum, and as on the average 170 horses were insured, the compensation paid on claims by the company averaged only 5s. 2d. per annum per horse insured. For the disposal of the carcasses a contract has been made with a knacker, who pays £1 10s. for a large carcass and £1 5s. for a small one.

#### HORSES AND CATTLE ON RECLAIMED LANDS.

During the six months ended December 31st, 1914, 814 head of horses and cattle were depastured on the reclaimed areas under the control of the Irrigation and Reclamation Department. Of these 614 belonged to farmers, and 200 to the department.

The prices quoted in South Australia are for farmers' lots in the country, and those in Victoria for parcels on trucks Williamstown ; the quotation on February 4th for parcels on trucks, Port Adelaide, was 7s. 6d. per bushel. In New South Wales the price fixed by the Government, viz., 5s. for farmers' lots in the country, remains in force. The Western Australian official rate is 7s. 4d.

## DAIRY AND FARM PRODUCE MARKETS.

A. W. Sandford & Co., Limited, report on February 2nd—

**BUTTER.**—Prices further advanced during last month, and with the exception of periods of heat, which naturally affected the quality of consignments coming forward, the demand was on the whole decidedly good, the heavy turnover recorded a month ago being well maintained. "Alfa" is selling at 1s. 5d.; "Primus," 1s. 4d.; choice separators and dairies, 1s. to 1s. 2d.; well-conditioned store and collectors', 9½d. to 10½d.; heated lots, 9d. to 9½d. per lb.

**EGGS.**—Values reached a figure for January that has not previously been recorded for many years, this being due to the fact that the quantities arriving showed a decided shrinkage in comparison with the usual supplies for that month. Quotations—Hen eggs, 1s. 1½d. per dozen; duck, 1s. 2½d.

**CHEESE.**—In this line also prices were on the up-grade, and values represented a distinct firming. Present quotations are from 6½d. to 7½d. per lb. for large to loaf.

**HONEY.**—Since last month stocks have been just about cleared, and reports from honey centres seem to indicate that there will be a shortage in production as compared with last season. Values remain firm at late rates, viz., 2½d. to 3d. per lb.; beeswax, 1s. 2½d. per lb.

**ALMONDS.**—Very little trade is being done in this line, importations from Europe preventing extreme rates here. Prices are nominally—Brandis, 7d.; mixed softshells, 6½d.; hardshells, 3½d.; kernels, 1s. 2d. to 1s. 2½d. per lb., with very few offering.

**BACON.**—The shortage in pigs previously referred to seems to have become even more acute, and the demand has continued good at little better prices. Factory cured sides are selling at 10d. to 11d. per lb. Hams have met a good inquiry at 11½d. to 1s. ¼d. per lb.

**LIVE POULTRY.**—The penning during the month was very heavy, but unfortunately a big percentage of the birds were in poor condition, the result, no doubt, of the high price of feed. It is difficult for buyers to obtain sufficient supplies of prime table birds. Heavy-weight table roosters brought 3s. to 3s. 9d. each; nice conditioned cockerels, 1s. 9d. to 2s. 9d.; small and medium, 1s. to 1s. 6d.; plump hens, 1s. 4d. to 1s. 10d.; small and light, 1s. to 1s. 3d.; ducks, 1s. 3d. to 2s. 6d. for fair to prime; geese, dull at 2s. to 2s. 9d.; pigeons, 6d.; turkeys, from 6½d. to 10½d. per lb. live weight for fair to good table birds.

**POTATOES AND ONIONS.**—The potato market has eased very considerably, owing to exceptionally heavy crops now being dug in Victoria. Locally grown supplies are very meagre, and in Mount Gambier, where early crops are also ripe, the growers have not so far manifested much desire to dig at the prices offering. In the South-East rains are badly needed, or later crops will suffer very severely. **Onions.**—Fair supplies of onions have been forthcoming, and prices have gradually weakened in sympathy with the eastern markets. Present quotations are—Potatoes, £4 to £5 per ton of 2,240 lbs. on trucks Mile End or Port Adelaide. Onions, £9 per ton of 2,240 lbs. on trucks Mile End or Port Adelaide.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of January, 1915, also the average precipitation to the end of January, and the average annual rainfall.

| Station.                   | For Jan., 1915. | Av'ge. to end Jan. | Av'ge. Annual Rainfall | Station.               | For Jan., 1915. | Av'ge. to end Jan. | Av'ge. Annual Rainfall |

\* No report received during the month of January.

† Formal report only received.

‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

March 10th, and April 14th, 1915.

### EDITORIAL.

[It is regretted that, owing to the continued shortage of paper, it has been found necessary to considerably reduce the space allotted to reports of meetings. For this reason many very good papers, which under ordinary circumstances would have been printed *in extenso*, have had to be dismissed with passing mention. This applies more particularly in cases where the subjects have been lately dealt with extensively by other Branches and reported fully in the *Journal*.—Ed.]

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

Edited by GEORGE G. NICHOLLS, Secretary Advisory Board of Agriculture.

#### UPPER-NORTH DISTRICT.

(PETERSBURG AND NORTHWARD.)

MORCHARD, January 2nd.—A paper on irrigation, which had been published in the *Adelaide Stock and Station Journal*, was read by the Chairman. Members agreed that the well water obtainable in this district was generally suitable for the cultivation of lucerne, if applied by means of sprinklers. Where maize and sorghum were grown it was thought advisable to sow the seed fairly thickly, in order to counteract the effect of the wind.

MOUNT REMARKABLE.—The paper on "Mixed Farming," written by Mr. H. V. Sprigg, of the Morphett Vale Branch, and published on page 255 of the October, 1914, issue, was read and discussed by members, some of whom were of the opinion that summer fodder on fallow would reduce the water content of the soil.

WIRABARA, October 21st.—HAYMAKING.—In a short paper on this subject Mr. P. R. Hoskins stated that the crop should be cut when the grain was of full size. The hay was then fairly green, and contained a little grain. It should remain for a day or two before being stooked, 20 sheaves being sufficient for one stook. He favored the medium-size sheaves, tied as tightly as possible. A three-cornered haystack, built butts outwards, covered with galvanized iron, was best. He favored a binder with a double row of fingers, good substantial frame, rotary battery, and good knotter. Members discussed the paper at some length.

**MIDDLE-NORTH DISTRICT.****(PETERSBURG TO FARRELL'S FLAT.)****CANOWIE BELT** (Average annual rainfall, 20.04in.).

December 3rd.—Present: 12 members.

**LAYING OUT THE HOMESTEAD.**—A short paper under this heading was read by Mr. G. A. Noll. The house, he said, should be built on rising ground, in a convenient part of the farm, and the stables, sheds, &c., situated a fair distance away at the back of same. He then outlined a method of constructing the outbuildings. A few trees would beautify the homestead, and also act as a breakwind. Members discussed the paper. In reply to a question it was stated that neatsfoot oil, coachalene, and beeswax was a good leather preservative. In discussing the relative values of different wheats Yandilla King, Federation, and Jonathan were mentioned as being specially suited to this district.

**LEIGHTON** (Average annual rainfall, 16in. to 17in.).

December 5th.—Present: 14 members and two visitors.

**FARM IMPROVEMENTS.**—Mr. R. Earle, in a paper on this subject, described his method of laying out a farm, and gave some useful hints on the building of the stables, sheds, &c. Separate stalls were best for the horses, he thought. In discussing the subject, Mr. Jas. Earle was of the opinion that horses in separate stalls would do better on a smaller quantity of feed than if in a loose stable. Mr. S. Cordon also agreed with the paper on this point, but Messrs. M. Hogan and A. E. McWaters favored the open stable.

**MOUNT BRYAN EAST** (Average annual rainfall, 16in.).

November 28th.—Present: six members and three visitors.

**POULTRY BREEDING.**—Mr. J. Best contributed a paper. He favored the White or Brown Leghorns. When commencing it was necessary to obtain birds as nearly pure bred as possible. Only the best laying hens should be bred from, and the remainder should not have a male bird running with them, as infertile eggs were best for marketing. He would feed grain at morning and evening, and chopped greenstuffs, such as lucerne, at midday. Chicks should be hatched in August or September. For the first week they should be fed on hard-boiled eggs and bread crumbs, and then crushed grain and cut green feed might be given. A good supply of clean, fresh water should always be available. Good housing was very essential to the health of poultry. The houses should be warm, airy, and draught proof. A lengthy discussion followed the reading of the paper.

**WHYTE-YARCOWIE** (Average annual rainfall, 13.91in.).

November 2nd.—Present: six members.

**POULTRY ON THE FARM.**—In dealing with this subject in a paper, Mr. F. H. Lock stated that farmers generally did not devote enough attention to this source of income. In most instances the poultry kept on farms was of no particular breed or strain, and consequently not very profitable. If birds for marketing were the object, heavy breeds were best, but if eggs (which he considered the more payable) were the object, then a light breed should be kept. He preferred the White Leghorn, but the best breed would soon deteriorate if not properly attended to. The birds should be well yarded, and part of the yard should be sown with green feed, preferably lucerne. The fowlhouses should be built of iron, be warm, dry, and well ventilated, but not draughty. In summer time, shady spots should be damped for the birds to scratch in. Careful feeding was essential to good laying, and cool clean water should always be available. A ration of meat food should occasionally be given. A good plan to eradicate tick was to burn straw in the houses; this should be done several times during the year. Spraying with kerosene, or a mixture of kerosene and soapsuds, was also effective. When birds became infested, he had found placing them in a clean house, and liberally

feeding them with different rations, to be good. Birds that developed diseases and could not be cured within one week, should be killed. Superfluous cockerels should be got rid of when they were about six months old. Hens over two years of age, except the best layers, which should be kept for breeding purposes, should also be culled out. From autumn to the end of October was the best time for hatching. Chicks did not require very much attention if properly fed and yarded. He emphasized the fact that only infertile eggs should be marketed. In the discussion Mr. McGregor mentioned that he would plant pine trees round the fowl-houses for shade and a breakwind. These trees did not harbor tick.

#### WHYTE-YARCOWIE (Average annual rainfall, 13.91in.).

December 5th.—Present: eight members and two visitors.

**HARVESTING AND CONSERVATION OF FODDER.**—A lengthy paper under this heading was read by Mr. W. G. Mudge. Comparing the reaper with the harvester, he stated that with an 8-ft. reaper a large area could be covered in a short time. Reaping could be commenced early in the season, as the wheat would ripen in the heaps. This machine did not scatter the weed seeds to the extent that the harvester did. Combined with a motor winnower the reaper was rather expensive. He therefore advised farmers who cropped anything less than 250 acres to use the harvester, although the reaper and motor winnower was the better for the man with a 500 or 600 acre crop. As far as the conservation of cocky chaff was concerned, he saw little difference between the two machines. A carrier placed on the back of the harvester would catch most of the cocky chaff, a bag being placed over the carrier on windy days. A good method to obtain a stack of straw was to take off 50 to 60 acres with the binder, while the straw was of good color, and before it had lost its nourishment, and put this through the header. The straw thus obtained would be almost as good as hay. A good plan was to build the straw-stack over the cocky chaff, which would then keep for many years. The paper was well discussed.

**BELALIE NORTH, October 31st.—QUESTIONS.**—Members thought the best way to deal with white or salty patches was to cover them with farmyard manure. Members generally thought that if the land was cross drilled less seed and super. would be needed. Some considered grading involved too much time to justify it, whilst others thought that it paid the farmer to grade his seed.

**(CRYSTAL BROOK, January 2nd.—WHEAT AND THE WAR.**—Mr. Billinghamst, B.A., read a paper written by the Superintendent of Agriculture, Victoria (Mr. A. E. V. Richardson, M.A., B.Sc.), and published in the *Victorian Journal of Agriculture*, December issue, page 705. Members were very interested in the paper, which was freely discussed.

**LAURA, October 2nd.—Co-OPERATION.**—This subject was dealt with in a paper by Mr. W. G. Pledge, in which he outlined the advantages which accrued to the community which adopted this principle. As a particular instance he mentioned the beneficial effect to the beekeeping industry, which had followed the formation of the S.A. Beekeepers' Co-operative Union.

**LAURA, November 6th.**—The Hon. Secretary (Mr. R. J. Rose) contributed a paper dealing with irrigation on the Murray. He referred at length to the excellent result which had attended the efforts of blockers there to cultivate fruit and vines by means of irrigation. Renmark, he said, now produced £100,000 worth of fresh and dried fruit annually. An area of 5,000 acres maintained a population of over 1,000 persons. Prior to being brought under irrigation the land carried principally mallee scrub, titree, and boxwood; and there were thousands of acres of similar country which could be equally profitably utilised. The paper concluded with a statement of a number of actual results of cultivation at Renmark.

**PORT PIRIE, January 16th.—DESTRUCTION OF ICE PLANT.**—Mr. J. Grieg had found the best means of destroying this weed was to trample it to a pulp. On level

country it might be effectively killed with the roller. The same gentleman contributed a paper dealing with the seasonal conditions which existed during the past year, and urged on members the wisdom of cultivating and sowing their land in the hope of a return of better conditions this year.

SPALDING, November 20th.—A paper dealing with co-operation was contributed by Mr. J. J. Gale.

YONGALA VALE, November 2nd.—STACK BUILDING.—A paper was contributed by Mr. Charles Davies, who dealt exhaustively with the subject of stack-building. He emphasised the necessity for careful attention to the roofing, and also the provision of tarpaulins to protect the hay from the weather whilst the stack was in course of construction. The sheaves should be tightly tied in the centre. When the stack had reached a height of about 8ft. it would be found advantageous to sprinkle the corners with water, thus tending to obviate trouble through corner sheaves slipping.

## LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

### BEAUFORT.

November 26th.—Present: 10 members and one visitor.

Mr. P. Underwood read a paper on haymaking. He recommended King's Early, King's Red, and Triumph as good hay wheats. If an early variety were sown, this could be cut, and the greater portion of it carted, before the grain harvesting commenced. The land intended to carry a crop for hay should be carefully cleared and well worked. For taking off a crop, if it were well grown, the best machine to use was the binder, as it was necessary to chaff good strong hay, in order to get the best from it. If, on the other hand, it was short and poorly grown, the grasscutter would be the best machine to use, as the hay could be fed loose. As a general rule he had found about five tons of hay sufficient for each working horse for the year. He preferred stooking about half a day behind the binder, the stooks consisting of about 15 to 20 sheaves. Mr. A. Yard, in discussing the subject, advised growing early wheat for sale, but for feeding horses on the farm Marshall's No. 3 would be found the best. Mr. G. Underwood recommended preparing the land well, and putting a light roller over the crop shortly after it had germinated. Triumph, King's Early, and Marshall's No. 3 were good hay wheats, in his opinion. Mr. J. Sampson thought Cape oats made the best hay, and Mr. A. Battle preferred the Algerian oats, which should be left to ripen before being cut. Other members discussed the paper at considerable length, and a good deal of valuable information was elicited.

CLARE (Average annual rainfall, 24.30in.).

November 27th.—Present: 21 members.

FODDER CROPS.—The following paper was read by Mr. C. E. Birks:—"The growing of fodder crops is one subject to which far too little attention is given when we consider the extent of suitable country we have from Mount Gambier to, say, Gladstone. In this area it is claimed that 'mixed farming' is carried on to a considerable extent, but the mere fact of sheep and cattle being kept on a wheat farm does not constitute it a mixed farm. If fodder crops do not play an important part in the working of the farm then it can hardly claim the title. Whether mixed farming proper pays in a general sense is too big a point to prove in a paper in one evening, and it is not the object of this paper; but I say candidly there are men in South Australia who can make it pay, and, also, there is no doubt it is the class of farming that would, when once established, be the best for South Australia, when carried on under a rainfall of not less than 15in. average. Now, in dealing with forage crops, let it be understood that it is only on that class of country we are dealing with, and even here some modifications might be expected,

viz., soils of a non-retentive nature, with a 15-in. rainfall, naturally are not going to give us good results as a retentive one with the same fall. Take, for instance, a light loam or sandy soil, with a good retentive clay underlying it, as against a limestone rubble soil, with no clay, or a stiff clay soil; though all these may occur in the 15in. rainfall, no one would expect as good results in the last two, with a minimum of rain, as in the case of the former; so that discretion is needed. It will be found an advantage to classify all fodders, in order to enable us to deal with them in discussion the more easily, and I would suggest a table something after the following style:—

| Summer.  |         | Autumn.  |             | Winter.  |             | Summer.  |             |
|----------|---------|----------|-------------|----------|-------------|----------|-------------|
| General. |         | General. | Particular. | General. | Particular. | General. | Particular. |
| Maize    | Barley  | Rape     | Barley      | Rape     | Barley      | Rape     |             |
| Sorghum  | Oats    | Mustard  | Oats        | Mustard  | Oats        | Oats     | Mustard     |
| Millet   | Lucerne | Peas     | Wheat       | Kale     | Rye         |          |             |

A crop that is good for all stock we will call a 'general' crop; those which are used more exclusively for sheep, say, 'particular.' There may be others that can be added, but to deal with all these would take a long paper. A little explanation here will not be amiss. All the crops that are hardy enough to stand the summer are of a nature that all stock relish and do well on. In the autumn (second column) we have peas. These would be grown the previous year, and held over to be eaten in the dry stage. Again, peas appear in the first column of the spring crops, because they can in their green stage be made use of by all stock. Rape and mustard appear in the first column in winter, but they would only be growths that had been fed off once, and had had time to get a good root growth, otherwise big stock only pull them up. The same applies in some cases with barley and oats in the autumn growths, and these crops can only be grown fit for feeding off at that time, and only when exceptionally heavy rains fall in January or February, and the ground has been ready and well worked for those crops. To those living in cold and wet districts this table would not appeal as much as to those farming in the milder parts of South Australia; but with certain alterations, according to circumstances, it may be helpful at getting at the crop we require for our particular purpose, taking into account the district we are working in. In fixing on what crops we are going to grow, suitability of soil, &c., and the purpose for which they are intended, must be our guiding points. Granted our soil is suitable for the bulk of the crops mentioned, the uses to which they can be put are manifold. Firstly, for the general improvement of the carrying capacity of the farm; secondly, fattening lambs, and topping up bullocks or the old dairy cows. Now for all these purposes there are three that are pre-eminently suitable—barley, oats, and lucerne (where it can be grown). Before going further, let me state that to get the most out of fodder crops we must be prepared to either fence into small paddocks, or have a system of movable fences, for if only one kind of crop is grown better results are got from 100 acres in three pieces than 100 acres fed off as one. *Autumn Sowing.*—Say we start with barley in the month of February. The stubble land by this time has been fairly well run over by stock, and if it has been well fallowed, in a great many instances, after clearing up the straw or hay stubble, the drill could be put to work to sow 1½bush. to 2bush. of Cape barley per acre. This, with any wheat shaken out, will give, with anything like decent rains in February or March, a good picking in a few weeks. By having the land divided up one can get the stock on much earlier than if they had the run over the whole of it. Another paddock worked up with

the rain that started the barley can be sown with 2bush. of the same cereal, and with these two sowings for winter and spring feed, the natural grass is being allowed to get ahead, so that it can be reserved, or some of it, for the summer and autumn, and there are few better ways of conserving food for one year only. With lucerne as a permanent crop, it is almost a business in itself, for the man who can grow it successfully has a very good income without troubling about much else. But it can be made use of by sowing with the wheat crop, or just after the first rain after the wheat is sown, providing the wheat is not coming through. In this way a fair crop of lucerne can sometimes be had by sowing 5lbs. to 8lbs. of seed per acre. According to kind of season these crops (barley and oats) can be fed off for varying periods of from two to five months. Barley will stand more feeding than the oats, but each of these can be fed off several times, and then sometimes a fair crop can be reaped. In normal years rye could also be sown in the autumn at the rate of 1½bush. per acre. It comes away early, and feeds off well if not allowed to run up too much. Peas, in suitable districts, can claim to hold their own against any when fattening forward lambs or stores, say, in December, January, or February, is concerned. They also make good feed in their green state, but, if possible, it will pay better to hold them over till they ripen. One of the great advantages with peas is that a farmer can buy stores, or has a better chance of buying, than with many other crops, say, rape, mustard, kale, or even barley. When the peas are ready to be fed off they can be left for weeks; not so with the other crops, for which a man must buy sparingly, lest his crops should not hold out, as their feeding capacity depends on their continuous growth, not on their mature growth, as in the case of peas. Rape and mustard should be sown in separate paddocks, 4lbs. to 6lbs. of the former and 5lbs. of the latter, in well-prepared soil. Mix the seed with the manure only as it is used, and then with free-running manure; sow lightly, then roll and harrow. The season of sowing depends a good deal on locality. The warmer the climate the greater is the range of time for sowing—from February to August. We will pass over grasses, for though of so much importance, the area over which they are likely to be successful is limited. *Summer Crops.*—Then, coming to the summer crops, these, to be a success, must be sown on fallowed land, or particularly-favored spots, such as river flats and hollows. Sorghum sown at the rate of 6lbs. to 8lbs. per acre will sometimes give enormous yields, and when this is the case, as much as possible should be cut as hay and used as chaff; mixed with wheat hay chaff it makes capital feed. Cut green and chaffed into a silo is also an economical way of conserving fodder. When fed off care should be taken not to turn stock in while too young if they have not got used to it by degrees. Millet can be worked the same as sorghum, but less seed per acre should be sown, i.e., 3lbs. or 4lbs. Maize needs moister land, and takes a special drill to sow it, but is one of the best summer fodders. As in successful wheat growing, so in fodder growing, it is the careful, painstaking man who makes a success of it, and because some men fail, it is not fair to blame the crop. This matter and that of irrigation are the two burning questions that have to be faced in the future, and this season instead of being a drawback to that improved state of affairs, should be an object lesson that we will never forget. Let us make up our minds to grow more, use more, but conserve more feed by means of silos and stacks, and then a year like 1914 would not have such an appalling effect on the country." In reply to questions, Mr. Birks stated that the Grey Dun was the best variety of peas to sow, and gave an instance of where he had seen the cattle eat the green haulms greedily; he also stated that it was a good plan to fallow land for summer crops, and he considered that the fallowing should be done in July. The best time for cutting (that was for the first time after sowing) a lucerne crop, was when the plant was in bloom. He always preferred cutting lucerne to feeding it down with stock. Furthermore, it was not absolutely necessary to fallow land for a lucerne crop, providing the land could be worked down to a fine tilth. The best time to sow lucerne was in June and July in warm districts; in this locality he thought the best time was in September or October. It was a good risk to sow 3lbs. or 4lbs. of lucerne seed per acre with wheat, as sometimes it provided a good stand of feed; but lucerne sown this way rarely lived over two years. If sowing lucerne on land where it

could be irrigated he advised sowing 8lbs. to 10lbs. per acre. He favored watering lucerne a week before it was cut, as then it came away very quickly after, and it would not take so long for the young growth to cover and protect the crown of the plant from the heat and sun. Lucerne could not be irrigated too much, provided the land on which it was growing was well drained. The best time to turn stock in on maize was when it was beginning to cob, as it was then in its most nutritious state. He advised sowing 2bush. of maize seed per acre, when it was to be fed down. Sorghum hay chaffed down made one of the best chaffs he had ever seen, but it was too strong by itself, and required toning down. He did not favor mangold wurzels for pig feed, as they were too washy; he preferred rape. Peas were good feed for topping pigs off for market, but where the meat was required for home consumption he did not like them, as they made the pigs too fat.

#### NANTAWARRA (Average annual rainfall, 15.90in.).

October 29th.—Present: nine members.

The meeting took the form of a question evening. Mr. Sleep stated that the best time to cut hay was when the grain was nearly ripe. Mr. E. J. Herbert considered that working horses did not do so well on green hay as on that which had been well matured. Mr. J. H. Nicholls informed members that last year he had not cut his hay until the grain was nearly ripe. The horses had not done too well on it, and sore shoulders had been prevalent. However, it was not advisable to cut too green, or too much weight would be lost. He would cut it so that the grain would be about half its matured size when the hay was dry. Mr. A. F. Herbert had found that horses did better on well-matured oaten hay than on oaten hay cut in any other stages. With reference to horses rubbing themselves, Mr. J. H. Nicholls considered that this was often caused by feeding the animals on food that was over-heating, although it appeared natural for them to rub off their old coats at certain periods. Mr. Sleep thought it due to too much dry food, and Mr. E. J. Herbert stated that on account of shortness of green fodder the horses got out of order, and itching resulted. Mr. W. Smith said that rubbing might be attributed to vermin, and would wash the affected animals in a weak solution of phenyl and water. An injection of two tablespoonfuls of turpentine and a pint of water was a good remedy for itchiness.

**HEADING WHEAT.**—Mr. Sleep said it would be difficult to head the short and irregular sheaves of this year's crop, and that it would be better to thresh the wheat out. Mr. J. H. Nicholls stated that when heading a fair quantity of the grain should be left in the hay. Mr. F. J. Sutton would not cut the hay until it was fairly ripe. Last year, when rust was prevalent, he found that that which was cut for hay contained better grain than that which was reaped. It was a good plan to take out the best of the grain when chaffing the hay, by placing a winnower, with harvester sieves adjusted, just under the elevator of the chaffcutter, and adjusting the winnower to the engine. He had not experienced much difficulty with white heads in damp weather.

**SEED WHEAT.**—Mr. Sleep thought sufficient care was not taken to keep varieties of wheat true to type. Mr. R. D. Nichols advised the hand-picking of a small plot, and working on that as a basis. If a change of seed were obtained from another district it should be similarly dealt with.

**STOCK TROUBLES.**—Referring to colic in horses, Mr. Smith said that there were several kinds of colic, the worst of which proved fatal in a few hours. He recommended treating affected animals with soda and chlorodyne. In a discussion on the effect of sand on horses, Mr. Smith stated that scouring should not be taken for a sign that the sand was shifting, even though a little might come away. If the sand had set he would put the horse on its back and pommel its stomach.

#### WATERVALE (Average annual rainfall, 27in.).

November 30th.—Present: 11 members.

**EXPLOSIVES IN THE ORCHARD.**—Mr. W. H. Smith read an article on this subject from the *Fruit World* of June 1st, 1912. A lengthy discussion followed, in which

Mr. Guthrie stated that to loosen the earth round the roots of full-grown trees he had exploded gelignite about 3ft. from their trunks. This course was effective, but there was a danger of the trees dying if the explosive were used in very dry seasons. Mr. E. E. Sobels (Chairman) advocated the use of explosives for stirring up the soil at the bottom of the holes before planting young trees. Mr. F. Burgess would dig the holes just large enough to take the young trees, which should be put in to the same depth that they had been growing in the nursery. The ground should be worked well to a depth of 6in. Members generally agreed that the soil should be fallowed before planting.

**BLTYH, September 2nd.—WOOLCLASSING ON THE FARM.**—The Hon. Secretary (Mr. J. H. Pratt) contributed a paper in which he outlined the necessity for, and method of classing wool on the farm. Two different types of wool should on no account be placed in one bale, he said. The best quality fleeces should be baled, and branded "firsts," and those possessing a superabundance of yolk, or otherwise not up to the standard of "firsts," should be branded "seconds." Bellies and pieces should be kept separate, and classed into two grades. An instructive discussion followed the reading of the paper.

**MALLALA, January 4th.—CO-OPERATION.**—The two papers on this subject which were written for the Annual Congress were read and discussed. Members considered that the present method of purchasing their machinery, &c., was very unsatisfactory, and that by co-operation they could obtain the article at a lower figure. **HARVEST REPORT.**—On account of the adverse season this report was not very satisfactory. This district had not averaged more than one bushel per acre. Insufficient hay for local requirements had been cut.

## WESTERN DISTRICT.

**GOODE (Average annual rainfall, 12in. to 13in.).**

November 5th.—Present: eight members and two visitors.

The meeting was held at the homestead of Mr. W. Folland. The standing crop was inspected by members, and it was noticed that the early-sown portion was the only part likely to give any return. That sown in June had turned out a failure. Afterwards Mr. Folland read a paper on selection of seed wheat. He emphasised the need of exercising care when selecting seed. The best time to do this, he said, was during harvest, while the grain was still in the head. Seed should be chosen from a uniform crop, free from all rubbish, drake, oats, barley, or different varieties of wheat. The different varieties of seed should be kept separate. When stripping and winnowing wheat intended for seed, it was important to see that the machines were absolutely cleaned out before commencing operations. The bags in which the seed was to be placed should also be well cleaned. Preparatory to storing he would screen the seed. If the farmer had to purchase his requirements he should very carefully examine the seed. If a particular variety was required, it was a good plan to inquire through the *Journal of Agriculture* where that particular variety was obtainable.

**KOPPPIO (Average annual rainfall, 22.40in.).**

December 3rd.—Present: nine members.

**SAND IN HORSES.**—Mr. J. J. Liddy contributed a paper on this subject. He referred at length to the remedies which had been adopted in different parts where this trouble was encountered, and also explained the nature of the trouble itself. His own experience was that the simplest cure, and one that he had not known to fail, consisted of drenching the affected animal with two or three pints of fresh milk. Generally one dose would be found sufficient; but, if not, the treatment could be repeated. Several members had

found pollard very effective in cases of sand, but it was generally admitted that new milk and honey constituted the safest cure.

**MANURIAL DRESSINGS.**—The effect of heavy dressings of super. on wheat in a dry season was discussed, and it was generally agreed that dressings up to 2cwt. at least would not be detrimental to the wheat plant under dry conditions.

**YADNARIE** (Average annual rainfall, 14.09in.).

November 28th.—Present nine members and three visitors.

**JUDGING AT AGRICULTURAL SHOWS.**—This subject was dealt with in a paper by Mr. S. H. Pearce. It was contended that a good deal of dissatisfaction which frequently existed with exhibitors could be obviated if judges adjudicated from a set standard for certain definite features, and made the cards with the points scored available to the exhibitors. When the defects of the exhibit were not pointed out, one of the most valuable objects of the show was defeated. He suggested, for illustration, that the maximum points for dairy cows should be set out as—Appearance 5, age 5, ease of milking 5, &c. A uniform system might be brought about by the Government requiring each society receiving a Government grant to adopt the method recommended. Members discussed the subject, and generally agreed with the opinions expressed therein.

**EXPERIMENTAL PLOTS.**—Mr. J. J. Deer, who had conducted experiments on behalf of the Branch, gave the following results:—

| Variety.               | Variety Tests.     |                        | Yields.<br>bush. lb. |
|------------------------|--------------------|------------------------|----------------------|
|                        | Seed.<br>per acre. | Super. per<br>acre.    |                      |
| Gluyas . . . . .       | 60lbs.             | 60lbs. mineral         | 9 0                  |
| German Wonder . . .    | "                  | "                      | 7 30                 |
| Jacobs No. 4 . . . . . | "                  | "                      | 6 30                 |
| Variety.               | Manurial Tests.    |                        | Yield.<br>bush.      |
|                        | Seeding.<br>lbs.   | Manure.                |                      |
| Gluyas . . . . .       | 60                 | 100lbs. mineral super. | 9                    |
| Gluyas . . . . .       | 60                 | 60lbs. mineral super.  | 9                    |
| Jacobs No. 4 . . . . . | 60                 | 100lbs. guano super.   | 7½                   |
| Jacobs No. 4 . . . . . | 60                 | 60lbs. guano super.    | 6½                   |
| Jacobs No. 4 . . . . . | 60                 | 60lbs. mineral super.  | 6½                   |
| Jacobs No. 4 . . . . . | 60                 | No manure.             | 3                    |

**KOONIBBA.**—Members discussed the different methods of working fallow. June was considered the best month for this work. It was agreed that the harrows should be used after each rain.

## EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

**COONALPYN** (Average annual rainfall, 17.49in.)

January 8th.—Present: six members and seven visitors.

**FIRE RAKES.**—The Hon. Secretary (Mr. F. Tregenza) read a paper on this subject. He referred to the different rakes on the market, and mentioned the various features of advantage in each. After describing the manner in which the implement was worked, the paper continued:—"When the paddock is cleaned up after stripping, and the stock have been on just long enough to secure the pick of the feed, and knock down some of the stubble, the first very hot day should be chosen to fire the paddock. A strong wind is not necessary, as where one gains by raking against the wind, one loses when going with it. As much as possible one should avoid the wind blowing behind the rake. As the tynes jump a stump burning stuff is dropped out among and around its shoots. Some have had to re-

sort to the practice of knocking the straw flat with a rail prior to raking. Under some circumstances perhaps this would not pay. With a two-row rake an average three or four bushel stubble could be dealt with. When working on thick stubble it has been found that the single row of tynes is best. With the double row the burning straw is not let through quickly enough, with the result that the flame is smothered. In my opinion it pays every time to fire-rake where we have shoots in a stubble which is thick enough to burn. As yet we have only spoken of the rake as a shoot destroyer, which, of course, is its chief work, but there are other advantages we reap from fire-raking. It sweetens the ground, and burns up rubbish which would be a hindrance in ploughing and seeding operations. Besides, it is the best means of eradicating that most dreaded of fungus diseases, which is threatening us in these light, loose soils—takeall. It might be argued by some that fire-raking means the destruction of good dry feed. Admitting that it does, the loss is far more than made up by the benefits derived, together with the improved self-sown and natural feed, which generally follows a good fire-raking. Every scorched clump of shoots means moisture conserved. Very little self-sown grain and other seed is injured.

GERANIUM (Average annual rainfall, 16in. to 17in.).

November 28th.—Present: 14 member..

POULTRY ON THE FARM.—Mr. H. Perrin contributed a paper. He advised farmers, especially those in new hundreds, to go in for poultry, which was a profitable sideline. If eggs were the object, he recommended the White Leghorn. The Silver Wyandotte was a good all-round bird. He would build the fowlhouses of iron and stone. This class of house was warmer in the winter than the all iron structure. He strongly deprecated the practice of allowing the poultry to roost in trees, on machinery, &c. The birds should be liberally fed; green feed forming portion of their ration. A few selected hens only should be bred from, and hatching should be done early in August, preferably by means of the incubator. The chicks should be kept separate from the old birds, and be fed on dry crushed wheat and chopped green feed, lucerne for preference. A plot of lucerne 12yds. square would be sufficient for 100 birds. The hens should be culled out after their second year. In conclusion he mentioned that farmers should be able quite easily to make a net return of from £50 to £100 per annum from poultry if they were properly managed.

#### McNAMARA BORE.

December 6th.—Present: eight members and three visitors.

VEGETABLE GROWING.—A paper dealing with this subject was contributed by Mr. H. Sanders. He advised those who contemplated growing vegetables to select a piece of loamy soil, preferably in a hollow. In the absence of a natural breakwind one should be erected. About a foot of stable manure should be worked into the soil in 2in. layers, and a quantity of super. and nitrate of soda should be applied. For winter and spring varieties of cabbage he preferred Henderson's Succession and Drumhead. Seedbeds should be prepared slightly below the ground surface, and worked very finely. The seed should be planted shallow, and watered through a branbag, which should be left over the seed until it had germinated. The plants should be shaded until they were strong. The variety of lettuce best suited to this district was Early New York. These should be sown in trenches, thinned out to about 6in. apart, and protected from the sun until well established. Potatoes did not do well here in the winter, but he would plant Pink Eyes, Redskins, or Carmens in the summer. If plenty of water were obtainable for irrigation Up-to-dates and Bismarcks should be planted. Onions did well. Seed should be sown in February or March. He favored White Spanish for early use, Brown Globe for late, and James' Keeping for storing purposes. Turnips could be sown throughout the whole year. They should be planted in rows, and thinned out to about 6in. apart. Good rich soil, with plenty of manure worked in, was essential. White Snowball was the best variety for this district. Swedes should be grown in the same manner. Sandy soil with old stable manure worked in, was best for carrots and parsnips. Early Sunrise peas should be planted in February, and be well watered. In June and July Yorkshire Hero and William Hurst varieties

should be planted. The crop should be put on new land each year, as it greatly benefited the soil. Broad beans should be sown in good, rich soil, and be well protected from the wind. French beans did not do very well. They should be planted from October onwards in shallow rows, and watered freely up to time of flowering. A sprinkler should not be used. He preferred to mulch the soil instead of using a hoe. Tomatoes required a well-prepared seed bed. After the plants had reached the flowering stage, they did not require much water. For rhubarb a trench should be dug to a depth of 30in., and filled in with plenty of manure and bonedust, well mixed with soil. For growing celery, also, a trench from 18in. to 2ft. deep was necessary. The seed should be planted in rows, and as the plants grew, brown paper should be wrapped round them; this would keep them white. Thousand-headed kale, silver and sugar beet, did well on very little water. All the vegetables mentioned, he said, would grow well if supplied with bore water, but they should be kept well watered, otherwise salt would accumulate in the surface soil.

#### MINDARIE.

December 7th.—Present: 12 members.

**CLEARING MALLEE LAND.**—Mr. Mann read a paper. For clearing mallee land he preferred rolling with a 10ft. roller 2ft. 6in. in diameter, and constructed of 5-16th in. steel, with a fairly heavy frame. This would require a five-horse team—two in the lead, two in clump, and one in the back. Under ordinary circumstances 15 to 20 acres should be rolled per day. The area rolled the first year should be at least 250 acres, which area could be easily managed by one man. The cost of rolling this area should work out at about £20, but for the alternative of cutting the mallee the expense would work out at about £100. Adding the cost of cutting springbacks, snagging, and stick picking to the rolling, he considered this method of clearing the land 4s. per acre less expensive than cutting the mallee, which would run into about 8s. per acre (wages one man for one day). The only advantages of cutting were that there were no snags if the work were done properly, no springbacks, and a better burn was secured. In the ensuing discussion Mr. Lower considered that 12 acres per day constituted a fair day's rolling. Mr. Kluge favored cutting, as there would then be no springbacks to be dealt with. A good man could cut 2 acres per day. He considered cutting would cost 5s. 6d. per acre. Mr. Parker considered a roller 2ft. in diameter quite large enough. The smaller roller made a better job and left fewer springbacks and snags. With a six-horse team, working two abreast, he would roll from 12 to 15 acres per day. The difference in cost of rolling and cutting, he said, was practically nothing, but rolling was quicker. Mr. Francis thought a 2ft. 6in. roller too high, and would work a six-horse team. Burning should be done before the springbacks were dealt with. Mr. Fullston considered that a good man would cut two acres per day. Mr. Phillips would not work one horse at the back, as advocated in the paper.

#### MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

November 28th.—Present: 10 members.

**CONSERVATION OF STRAW.**—The Hon. Secretary (Mr. C. F. Altmann) contributed a short paper under this heading. He contended that straw was more valuable for feed than cocky chaff, and that it would keep longer. It should be cut with a mower, and then horscraked. He preferred to build it into circular stacks, of about six or seven tons, with rounded tops. Three or four weighted wires placed over the stacks would keep them compact. A post-and-wire fence should be placed round them to prevent stock from pulling them about. In the subsequent discussion some members stated that they preferred to cut the straw with the binder, as it would then be more convenient to chaff. Mr. Brandler considered that if cut with the binder it would be too hard for feeding long.

#### NETHERTON.

December 9th.—Present: 15 members and four visitors.

**WORKING NEW LAND.**—Mr. W. R. Peake contributed a paper. He advocated rolling the scrub during September or October, and burning off in February.

This should be followed by ploughing, a share implement being used for preference. Sowing should be commenced in May, at the rate of 30lbs. of late varieties, or 40lbs. of early varieties, per acre. If successive cropping was adopted, two crops of wheat, followed by one of oats, would be found best for new land. Oats was a crop immune to "takeall," which improved the grazing of the land if it were left out for a season, and provided good stubble for burning off. Stubble burning was an important factor, and if the stubble was thin the firerake should be used. The paper was then discussed, members being divided in opinion as to which was the better variety of oats—Algerian or Calcutta Cape. Early rolling was recommended, and it was thought wise to cut springbacks. A heavy share plough not only destroyed more roots than other implements, but it weakened the stumps that remained in the land.

RAMCO (formerly Waikerie). (Average annual rainfall, 8.89in.).

November 30th.—Present: 19 members.

QUESTION BOX.—Mr. A. E. Ross attributed the dropping of berries on  $3\frac{1}{2}$  year old currant vines this season to the dryness of the soil and absence of winter irrigation, followed by the sudden copious supply of moisture. These conditions had caused an unnatural rush of sap to the head of the shoots, which forced the berries off. To prevent this re-occurring, heavier and later cincturing should be adopted. He had cinctured a number of vines more heavily than others, and then re-cinctured them lightly after the irrigation with satisfactory results. He would not cincture sultanas. Mr. H. F. W. Lehmann considered that the dropping of the berries was due to cincturing at the wrong time. This should be done after the caps were on the ground, and the berries were well formed. Mr. J. J. Vasey mentioned that the vines had probably been cinctured too severely. Mr. J. C. Rowe attributed the trouble to too severe cincturing, followed by hot winds. Mr. A. E. Ross stated that the birds, especially sparrows, starlings, and crows, were becoming a great nuisance to the gardeners.

#### WYNARKA.

November 28th.—Present: 13 members and two visitors.

INCREASING THE WHEAT YIELD.—Mr. C. S. Hall contributed a paper dealing with this subject. With the adoption of a judicious rotation, he said, there was no fear of soil deterioration. He favored well-worked early fallowings, and alternately growing forage crops—for feeding off with sheep—and wheat. By feeding off forage crops each alternate year the organic contents of the soil were greatly increased by the animals' excrements. The land should also have liberal dressings of farmyard manure. He strongly advised farmers to select and grade their seed wheat to obtain best results. The growing of barley was then discussed. Members generally deprecated the practice of sowing large areas for grain when it was intended to sow the same land with wheat the following year, as the sample of wheat would be detrimentally affected.

LONG FLAT, November 30th.—The inaugural meeting of the above Branch was attended by Messrs. H. J. Apps and H. J. Finnis, of the Department of Agriculture. After the latter officer had delivered an address on the organization of the Agricultural Bureau, and outlined methods of working a Branch, Mr. Apps addressed the meeting on dairying. At the conclusion of both addresses a number of questions were asked and answered.

SHERLOCK, January 1st.—After a period of recess a meeting of this Branch was held on the above date, and a scheme of work for the future outlined.

WILKAWATT, January 9th.—QUESTION BOX.—In reply to a question, Mr. J. T. Tylor (visitor) explained the effect of gypsum on heavy, clayey soil. It was the opinion of most members that sheaves should be butts outwards when being placed in the haystack. Members agreed that shoots should be cut during February and March. Mr. W. R. Neville had found strychnine placed in pieces of apple or prunes effective in destroying foxes. It was a good plan

to trail a parrot (with feathers previously burnt), and bury baits along the trail.

WOODLEIGH, December 7th.—CO-OPERATION.—Mr. E. T. Smith contributed a paper on this subject. He was of the opinion that the different Branches of the Bureau should co-operate in the purchase of their machinery, &c. Members generally agreed.

### SOUTH AND HILLS DISTRICT.

CLARENDON (Average annual rainfall, 33.67in.).

October 30th.—Present: 13 members and one visitor.

The meeting was held at the homestead of Mr. A. Harper. Members made a tour of inspection of the farm. The crops, owing to the unfavorable season, were not up to their usual standard. Some oats that had had a double application of super. showed a marked improvement on that which had only received one application. Mr. J. Spencer's farm adjoining was then inspected, the potato plots receiving special attention. Those that had received a heavy dressing of lime gave promise of a much heavier yield than the untreated plots.

HARTLEY (Average annual rainfall, 15in. to 16in.).

December 2nd.—Present: 14 members and four visitors.

THE HOUSE FLY.—Mr. S. Beavis read a paper on this subject. He referred to the habit of this insect of breeding in manure heaps and other unwholesome refuse. As a means of transmitting disease germs it was perhaps unequalled. Strenuous efforts should be made to destroy the pest. Stable manure should be cleared at regular intervals. Kerosene or chloride of lime should be sprinkled over it. Scrupulous cleanliness in this regard would to a great extent mitigate the evil.

HARTLEY (Average annual rainfall, 15in. to 16in.).

December 30th.—Present: 16 members and two visitors.

OVER-STOCKING.—Mr. T. Phillips contributed a short paper on the subject of overstocking. He considered that the average farmer kept too many light horses about the place. A farm of 500 acres could be worked with seven good working horses. No more stock than could be properly attended to and fed should be kept, as a few animals in good condition were more profitable than a large number in a poor state. A discussion followed. In view of the changing seasons it was difficult to know how much stock to carry. When the season turned out a failure stock brought very low prices, and so much of it was still kept on the holdings. This was causing overstocking at present.

MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).

August 4.—Present: seven members and two visitors.

FALLOW AND FALLOWING CROPS.—The President (Mr. Wheaton) read a paper under this heading from which the following is extracted:—"It has been said that fallowing is not necessary on Kangaroo Island, and among the reasons given for this opinion a popular one is that we do not need to conserve moisture, this being the chief reason for fallowing in the drier districts. In a district like this the main point to be aimed at is the aeration of the soil, to induce the breaking up of organic matter through the agency of the numerous ferments. The country along the coast is good grass land, and will grow early feed. Then one would probably not get sufficient increase of crop to make up for the feed lost by fallowing, for the ground can be got in condition and a satisfactory yield of barley obtained the same year. Unfortunately this good grass land is very limited, and land away from the coast, excepting during very favorable seasons, will only produce good grass in the spring. I am convinced that better crops can be grown on this poor grass land by bare fallowing or growing fallow crops, than is the case with ground not ploughed until after the first rains. The feed one loses would

be more than compensated for by the production of a fallow crop on the old ground; while the rough and snoot-covered land could be bare fallowed, thus making two sections, each to receive different treatment. The first to be considered is the old ground, for it is on this that the fallow crops are to be grown. It is advisable to feed these paddocks down bare the spring previously, to get rid of the grass seeds, and so have them as clean as possible to start with. As soon as seeding is over the ground should be ploughed to a depth of not less than 4in. and then cross-harrowed, ready for cultivating before the crop is sown. I have had most success with peas, maize, and piemelons, and have also tried sorghum and pumpkins. In growing these crops it is well to remember that to be a success they must be put in well. Peas are the first, and should be sown not later than the middle of August. They can be grown on any soil. Not less than 2bush. per acre should be sown. As the crop is left till ripe, the weed seeds will also fall, and thick sowing is necessary to smother the weeds. Care must be taken to have the ground well cultivated before sowing the cereal crop. It is also advisable to have a fast-growing crop such as barley, or, if wheat, an early variety. On poor, sandy land I am trying one bushel of peas, and leaving the ground out for grass the following year before putting in a crop. Peas make splendid feed for fattening sheep, provided a good supply of drinking water is available. Early Dun is the best variety to sow. Maize and sorghum can be sown from September to November, according to the season. Maize sown at the rate of 4bush. to the acre in rows 28in. apart, can be grown on any loamy soil, which will hold the moisture. It makes excellent feed for all kinds of stock. When grown well, and fed off when quite green, it is very fattening. It has one disadvantage in that once fed down it makes very little second growth. Hickory King is one of the best kinds. Sorghum is slower growing, but will grow again after once being fed off; 4lbs. to 8lbs. of seed per acre, mixed with super. should be sown. Early amber cane is a good sort. Melons and pumpkins do best on sandy ground. I have found melons very effective to stop drifting on any patches that are liable to move with dry winds. They also have an advantage in that they can be kept till after the first rains when feed is scarce. Sheep soon take to the melons, which have to be cut open, for they do not seem to like the rinds. Plant the seed 16ft. to 20ft. apart each way. These crops should receive a dressing of from 80lbs. to 1cwt. of super. per acre. The work necessary to get the ground ready for sowing cereals varies. Cultivating twice with a share cultivator may be sufficient or it may be necessary to give it a shallow ploughing early, and then cultivate ahead of the drill. But as barley is the principal crop grown, there is time to get the ground clean. Ground intended for bare fallow should be ploughed not less than 4in. deep, have the stumps picked, and be then cross-harrowed. If no rubbish is growing it will not hurt until after harvest, when, if damp enough, it should be cultivated as soon as possible. This cultivating will kill any thistles or other weeds, and also put the ground in condition for any other seeds to grow. Shoots should now be cut and burnt, and the cultivator, preferably the share implement, should be worked in front of the drill. I feel sure the yield from fallow ground will be a long way ahead of that from land not so worked. My experience has taught me not to be in too much of a hurry to sow the fallow. The best crops of wheat have been sown not later than the end of June, and barley after that. I have had best results from the early to mid-season wheats sown later."

#### MOUNT COMPASS.

December 19th.—Present: 13 members.

**DAIRY HERDS.**—An address on this subject was given by Mr. J. D. McEwan. He urged dairymen to keep a herd of one breed only. If cream were the object he advised the Jersey, but for an all-round cow he preferred the Ayrshire. Herds could be improved by testing and selection. Heifers under two years of age should not be used for breeding purposes. They should be milked for at least nine months after their first calf before being again utilised for stud purposes. He deprecated the practice of close and in breeding. The Hon. Secretary (Mr. W. Cocks) advocated dairymen co-operating and purchasing the best pedigree bull they could, or else collectively guaranteeing a certain sum as service fees to any breeder who would obtain a good bull, such bull to be approved by the Branch of the Agricul-

tural Bureau. The latter idea was favored by members, who requested the Hon. Secretary to investigate and report on the matter.

#### MOUNT BARKER (Average annual rainfall, 30.93in.).

September 30th.—Present: 44 members.

**HANDFEEDING SHEEP.**—Mr. W. B. Stevenson contributed a paper dealing with handfeeding sheep. He pointed out the value of the droppings of these animals on the farm, and mentioned that where a system of handfeeding was practised for a period of two or three months during the year, as many as 20 sheep per acre could be kept. These would effectively clear the ground of such weeds as sorrel and stinkwort, especially where the latter was young. The chief crop grown for handfeeding in the Hills District was peas, and he mentioned that from an area of 35 acres sown to this crop, he secured a stack containing about 800bush., which eventually topped off about 900 sheep and lambs, whilst they were running on an area of 20 acres. Most of these sheep were bought as forward stores, and were kept on an average of six weeks. At the time the market price of grain was 3s. 6d. per bushel, and after deducting commission, railage, &c., a net profit of 3s. 9d. per head was secured. Continuing the paper read:—‘I am sure one can give sheep more grain than they will profitably return. Some farmers turn the sheep on peas when the crop is ripe, thus saving the cost of cutting, collecting, and carting out again. I would not turn sheep on a crop of peas grown on sandy land, that is, if the yield was fair. They soon cut up the surface, and the peas are buried. They certainly scratch for them, but still a lot are lost, and if rain should fall the grain will sprout. If the land has a fairly firm surface, there is not as much risk, and a good plan to adopt is as follows:—Supposing 10 acres of peas are ready to be fed off, subdivide this paddock into, say, four blocks, not all at the same time, for material might not be available, but using only one line of fencing, and when the sheep need more feed remove the fence. Iron posts and netting only are required for the purpose. Netting 3ft. high, of 3in. mesh, can be bought for about 10s. per 100yds. Iron posts can be procured at about 6d. each. Posts made of wattle answer fairly well, but iron posts are better. When the soil is damp enough I find it a good method to plough a straight furrow about 4in. deep where the fence is desired. Take the roll of netting and place it along the furrow, after which fill it in. Now place the iron posts in the ground about three yards apart, care being taken to drive them in to the correct depth, so that the netting can be stretched tightly to the top of the post, where a notch to receive same is provided. The fact of the netting being in the ground a few inches prevents the sheep getting under, and it is very rarely they will jump it. A fence of this description costs about 28s. per 100yds., and one man could make a good job of 200yds. in one day. Pig-netting is good, but it is more costly, and the usual height is about 2ft., which is not sufficient without fencing wire. I am sure it pays to subdivide in this manner. If the sheep are turned on to the whole block at once, the result is that within a few days all the peas are threshed out, the straw is soiled, and more peas are being trodden into the ground. If rain falls there is a mess. It is astonishing how long a good proportion of peas remains in the pods, if left undisturbed. Another method of feeding is to take the grain out in bags, and scatter it to the flock, or mix the grain with chaff, and feed it in troughs. I think it a good plan to mix the grain with chaff, using about 1lb. of peas and 1lb. of chaff per day per sheep. A good, cheap troughing is made by using bags and sawn timber in 12ft. lengths 1in. square, or straight wattles. Make a hole in two corners at the bottom of the bag, and place the timber through; then drive in a few nails or sew it with twine. Fasten this trough to a fence, making the troughing stand about 18in. from the ground. With troughs a man can feed his sheep with corn and chaff, and there will be no waste. It is not advisable to give grain only in troughs, as the sheep eat the corn too quickly. If mixed with chaff it takes them five times as long to eat it. I gave a few sheep 1lb. of corn alone each, and they devoured it within five minutes and wanted more. When it was mixed with an equal quantity of chaff they took much longer to consume the same weight. The sheep like a good sample of chaff, and they like it cut short. Long chaff will be found at the bottom of the trough. One would think that it would be advisable to soak grain before feeding, especially peas. I find this is not so; sheep object to anything damp. Peas have a slight advantage

over other grains as a foodstuff. Sheep may also be profitably fed on oats, wheat, barley, &c., and the best way to use these grains is to mix them with chaff, say pound for pound. A fair ration for an average sheep, for fattening is 1lb. of grain and 1lb. of chaff per day, and a little stubble if possible. For keeping breeding ewes in good store order, a little over half the above ration will suffice. I do not maintain that it pays to hand feed the same sheep all the year round. For topping up, or if the animals are really cheap, although perhaps poor, it often pays as well to feed them as to feed better conditioned and higher-priced sorts. It sometimes happens that a farmer finds himself short of feed in his grazing paddocks, between the seasons. It is at times then advantageous to give the flock corn and chaff, or perhaps chaff alone. Two pounds of good oaten chaff daily is not a bad ration for keeping sheep going until green feed is available. The cost of feeding and fattening sheep on 1lb. of grain (say peas), and 1lb. of chaff per head per day, will amount up to a tidy sum in a month. Take peas at 3s. 6d. per bushel, chaff at £3 per ton—30lbs. of peas per month at 3s. 6d., 1s. 9d.; 30lbs. of chaff per month at £3, 9d.; making a total of 2s. 6d. per month per sheep. So care must be taken in buying the stock, and feeding judiciously. At such a time as the present it would not pay to hand feed sheep on chaff at well on to £6 per ton, that is, if a fair price had to be paid for stores. When peas are below 3s. 6d. a bushel, wheat 3s. 4d., oats 2s. 2d., and chaff £3 per ton, rather than sell at those figures I would feed sheep, and put it into mutton or lamb and wool. That is if the buying price of sheep is at all reasonable. The last year or two store sheep have been too dear. Lately it has paid just as well (very often better) to buy lambs or sheep almost fat, and make them better, as stores, although poor, brought too much money to buy and fatten. It is astounding how quickly sheep become quiet, when hand fed, even though they have been accustomed to large runs. I once bought a line of 300 poor ewes in lamb. They had sound mouths, but were half starved. I put them in a 20-acre paddock on which there was scarcely any feed, but I put some chaff and oats in troughs for them. They did not know what it was, and would not eat it, preferring to scour the paddock in search of feed. I then fenced them in a small paddock with netting, put a few sheep that had been hand fed with them, and they were all feeding within two days. I have proved that sheep will take readily to grain and chaff, even when given a taste of a green crop the same day. I fenced off an acre of wheat, putting a few sheep and lambs on it in the middle of the day only, shutting them in an adjoining and small bare paddock, and feeding morning and night on oats and chaff. These sheep cleared up the ration. I think it advantageous to give sheep a little solid food when turned on a green crop, but as mentioned, they must be shut off to eat the corn and chaff, otherwise they will not touch it, preferring to fill themselves with green stuff. I consider it pays during the pea-feeding period to always keep a few sheep that are used to the grain, the same applying to all hand feeding, because they soon teach the newcomers how to feed. Otherwise some sheep might go off for a few days.

*Sheep Fed on Growing Fodders.*—Among some of the crops which are put in expressly for sheep-feeding purposes are rape, barley, rye, oats, wheat, and lucerne. I have found rape rather an uncertain crop in the Mount Barker district. If put in in autumn it must be very early to do any good for winter feed. It should be sown at the end of February or in March to provide much feed for winter, and, of course, if no good rains fall in those months, it does not germinate. However, it is a cheap seed, and it is perhaps worth while to risk sowing at the end of March with or without rain. If rain falls it soon germinates. Some prefer to sow rape at the end of August, September, or October. It is not likely to be cut with frost if put in in September, and there is a chance of getting green feed when the natural grass is dead. One disadvantage, however, is that rape is rather subject to a pest known as the cabbage aphid. This insect spreads rapidly. When it is prevalent a good plan is to subdivide the crop into small paddocks and feed it off bare to the ground, after which it should receive a good harrowing. If kept low for a while there is nothing left for the pest. This insect does not attack the rape in the winter. Rape is very fattening. It enriches the soil, acting on the ground similarly to peas. The cost of seed is generally 3d. to 4d. per lb., and from 4lb. to 6lb. will sow one acre. Barley, rye, oats, and wheat are all good crops for feeding off. These, if put in in March or April, under favorable conditions, viz., ground in good heart, well-worked, and with sufficient moisture, should be ready for feeding off in about five to seven weeks after germination. Rye and barley

are the earliest. Barley is the best for winter feed, but oats and wheat are the best at the latter end of the year. The carrying capacity varies considerably, according to the fertility of the soil and nature of the season. For this district about seven sheep to the acre (sometimes more, sometimes less) for six months is a fair estimate; that is if the crop is ready to feed off in the early winter, and a crop of oats or wheat if not ready until September for feeding should carry about 15 sheep to the acre for three months, but the paddocks *must be subdivided* to make the best of the crop. Generally speaking, in the Hills Districts it is rather wet for winter feeding unless the land is high, but during the last few years it has not been so. With lucerne one has to wait nearly a year before there is a good plant unless it is irrigated, and the best results are obtained by leaving the plants in the ground for several years. The lucerne flea, a winter and spring pest, causes trouble with this crop. Most farms will not stand continued cropping, and having the produce carted off the farm, therefore I think it beneficial to either hand-feed good sheep by carting out grain, &c., to them, or by growing crops expressly for them, and feeding them off with the paddocks.

*Class of Sheep.*—Most farmers about this district prefer to buy their lambs or sheep when required, rather than to breed them. Generally this is more profitable, especially on small holdings. I admit there are points in favor of breeding fat lambs for market, if a man possesses some rough grazing land within a reasonable distance of his farm. For fat lamb breeding the Shrop.-Merino is one of the best. The Leicester, Lincoln, and second cross are larger, but they require more feed. The Merino sheep is splendid for wool, but pure Merino lambs do not mature as quickly as the Crossbred. They all do well if well bred and well fed. If the buyer considers that the value of the various kinds of sheep is about equal, I would advise the purchase of Crossbred lambs for fattening. If on the other hand lambs are dear, and in the same market, say, sound-mouthed, poor, but healthy ewes can be bought at a low figure, I should buy the ewes. Aged wethers in my opinion do not do so well.

Where nature has not provided shade it is profitable to make some. A good plan is to build a shelter six feet high, using ordinary fencing posts, and 3in. x 2in. stringybark cross pieces, covering same with cheapest wire netting, on top of which a light covering of pea straw should be placed.

Cool fresh drinking water is very necessary in summer, especially when sheep are fed on corn, &c. If there are no creeks, have a trough of water under the shade if possible. I have a spring a few chains above the shelter shed. From this spring pipes are laid under the ground, thus providing cool water in a trough. A trough containing salt should be under the shade near the water.

#### NARRUNG (Average annual rainfall, 17in. to 18in.).

December 5th.—Present: 11 members and several visitors.

**MANAGEMENT OF FARM HORSES.**—Mr. S. Bottrill read a paper on this subject. He preferred a stable closed in on three sides only, and subdivided, so that at feeding time the horses could not interfere with one another. Each animal should have sufficient room to enable it to lie down, and be given an opportunity to roll occasionally. Before being fed a drink should be given. Close stables and rugs should be avoided, as horses were more likely to develop colds in these than in big, airy stables. A team working in the fields should be stopped at sundown. There was not much danger of sore shoulders if horses were well attended to, their shoulders kept well brushed, and collars fitted well and kept clean. Sore shoulders were sometimes caused by bad driving. He deprecated the practice of much shouting and whipping the team, and of jerking the reins. All teams should be driven with crossed reins. Harness should be overhauled and cleaned at least twice a year. A good preparation for this purpose was a mixture of fat black and neatsfoot oil.

#### PORT ELLIOT (Average annual rainfall, 20.33in.).

December 19th.—Present: nine members.

The meeting was held at the residence of Mr. J. Brown, Hindmarsh Valley. Before business commenced members were shown over the site chosen for the new reservoir by the Engineer in charge of the works, and were of the opinion that an

ideal spot had been selected. Mr. Brown's homestead and garden was then inspected, and members were particularly interested in that portion under irrigation.

**IRONBANK, December 26th.—PRESERVATION OF EGGS.**—A short paper on this subject was read by Mr. C. Morgan. The two best-known preservatives, he said, were lime water and a solution of liquid glass (sodium silicate). He preferred the former. The eggs should be kept in a cool place and be absolutely fresh when placed in the preservative, the surface of which should be protected from the atmosphere.

### SOUTH-EAST DISTRICT.

**TATIARA** (Average annual rainfall, 19in.).

**December 5th.**

**POISONING RABBITS.**—Mr. Bond, sen., recommended the following practice for destroying rabbits:—"Place as much poisoned chaff as would fill a jam tin in a piece of paper. Close the paper very loosely about the chaff, and thrust it as far as possible down the burrow. Then put sheets of paper down the burrow, and when satisfied that the sheets of paper block it up, fill it with earth and ram it down tightly on the paper wad. This method of rabbit-destroying will be found to be effective for closing up rabbit burrows. The following preparations can be used for poisoning the chaff:—Arsenic, half a kerosene tin of water, 1lb. common soda, 1lb. arsenic; boil till clear, then add 2lb. sugar, soak the chaff well in it, and dry it. Strychnine—Boil contents of bottle of soluble strychnine in three gallons of water, and add 1lb. sugar when boiling. Boil the mixture for 15 minutes. Soak the chaff till saturated and allow it to dry." In discussing the subject Mr. Sunman stated that he had found poisoned grain very effective. Members generally thought it dangerous to allow cattle to eat the bodies of rabbits that had been poisoned.

---

**WIRREGA** (Average annual rainfall, 19in. to 20in.).

**December 5th.—Present: seven members.**

The meeting was held at the homestead of Mr. Pitman. That gentleman read a short paper. Several varieties of grass, he said, were now growing and spreading well. He had noticed that those paddocks which had been cropped each year had produced better crops of both grass and wheat than those which had been laid to fallow every alternate year. Members discussed the paper and were generally of the opinion that ground continually well worked, whether left out to bare fallow or cropped each year, produced a better stand of grass after every additional working.

## AGRICULTURAL PUBLICATIONS.

The following publications have been issued by the Department, and are available for distribution at prices mentioned :—

Vinegrowers' Manual, by A. Sutherland, 6d. ; posted, 7d.

Reports of Conferences of Australasian Fruitgrowers held at Brisbane and Wellington, 1s. each, or 1s. 1d. if posted.

**Journal of Department of Agriculture of South Australia**, 1s. per annum, in advance ; 3d. per single copy to residents of South Australia ; 2s. 6d. per annum to other places.

Any of the following Bulletins and Leaflets may be obtained by sending a penny stamp for postage :—

Agriculture, Miscellaneous: Agricultural Bureau Congress Reports ; Amount of Spirits to be Extracted from a Ton of Raisins ; Depth of Sowing of some Agricultural Seeds ; Digestibility and Handling of Wheaten Hay ; Dry-Farming Conference Reports ; Feeding-Off Experiments with Sheep ; Housebuilding in New Districts ; Irish Potato Blight ; Lucerne Cultivation and Management ; Lucerne Leaf-Spot Disease ; Milling Experiments ; Reclamation of Land ; Roseworthy College Farm Flocks ; Roseworthy College Harvest Reports ; Roseworthy College Experimental Field Reports ; Sheep on the Farm ; Spraying against Potato Blight ; Stage to Cut Wheaten Hay ; Trial of Stone-Gathering Machines.

Horticulture : Banded Pumpkin Beetle ; Bordeaux Mixture ; Curculio Beetle ; Codlin Moth ; Currant Industry ; Fertilisation of Orchard Lands ; Fruit Drying ; Fruit Flies ; Fruit Preserving ; Grape Vine Mildews ; Gumming Disease of Peach and Almond Trees ; Selection and Planting of Fruit Trees ; Peach Leaf Curl Fungus ; Plums and Prunes ; Preserving, Canning, and Drying of Fruits ; Production of Early Tomatoes ; Remedies for Diseases of Fruit Trees and Vines ; Some Notes on Almonds.

Dairy : Milking of Cows ; Spaying of Cows ; Taints and Flavors of Dairy Produce ; Taints in Milk and its Product ; Testing Milk and Cream.

Stock : Branding of Stock ; Bot Flies and Bots ; Castration of Colts and Spaying of Cows.

Poultry : Diseases of Poultry ; Parasites of Poultry ; Poultry Tick ; Reports of the Egg-Laying Competitions ; Single Testing for Egg Production.

Beekeeping Notes.

**[Every farmer and fruitgrower should join the Agricultural Bureau. Write to Department of Agriculture for particulars.]**

## INQUIRY DEPARTMENT.

---

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

### STOCK INQUIRIES.

Replies supplied by Mr. F. E. Place, B.V.Sc., M.R.C.V.S.,  
Veterinary Lecturer.

"W. R. P." had horse which swelled under the belly, was not apparently in pain, but moped about for a week and then died. Subsequent examination revealed some sand in bowels and that swollen parts were bloodshot and slack. He asks cause of death.

Reply—Breaking down of blood tissue was the cause of death, and this was brought about by poisons formed by worms and a diet deficient of vitamins. Treatment, as preventive of similar cases, lucerne, maize (green or dry), sorghum. Bone meal four parts, saltpetre one part, as a lick or 2ozs. mixed with each feed for a week or so.

"J. V. K." asks for treatment for 3-year-old colt which is doing badly, is dull in coat, has lampas, and is not casting front nippers.

Reply—Constitutional upset due to teething. Draw or knock out <sup>the</sup> nippers so as to give the permanent teeth room. Try and get him to take bran mash each evening for a week or two. Give as much grey <sup>powder</sup> of (mercury and chalk) as will lie on a shilling once a day for a fortnight, and other symptoms will gradually disappear. Never mind the lampas, its effects died when St. George killed the dragon.

"C. A. H." has horse, 7 years, which apparently is in good health, his coat is smooth, but the horse does not eat well, is losing condition, and eats dry dung.

Reply—The trouble is indigestion. The treatment—Put on bran mashes only for two days, then give 5 dram aloes ball, and when scouring ceases give once a day in feed a tablespoonful of the following mixture :—Sulphur, 1 part ; sulphate of iron, 1 part ; gentian, 1 part ; black antimony, 1 part ; sugar, 8 parts.

"G. A. A.," Wilkawatt, asks treatment for horse that has had one of its eyes injured by flick from whip.

Reply—Mix 1oz. tinct. arnica with  $\frac{1}{2}$  pint methylated spirit and  $\frac{1}{2}$  pint water, hang a cloth from the forehead band of bridle over eye and keep damp with lotion. The eye will clear in a few weeks. The scum is in, not on, the front of the eye, and do not use sugar glass or any other similar cure.

"E. A. S.," Booleroo, asks treatment for 4-year-old mare suffering from cough, running nose, slightly swollen throat, and feverish; she eats fairly well, but is stiff over loins and languid; hind legs swollen.

Reply—In a 4-year-old mare the symptoms are more likely to be strangles than influenza, but it is more than possible that worms are also part of the mischief. Dip a rag in Stockholm tar, wrap it round the bit, and leave in the mouth for a few hours at a time. Continue the saltpetre or Epsom salts, but not both, preferably the latter. Rub warm lard into the throat swelling. Later give a tablespoonful of Fowler's solution of arsenic once daily in food for a week or two.

"F. C. T." had several horses suffering from creamy discharge from nostrils, a short cough, heavy breathing, and loss of appetite for food or water. Two died, and the *post mortem* showed sand, bots, blood worms, and throat and lungs crammed full of yellow fluid.

Reply—The symptoms of pneumonic influenza which is connected with worm invasion. At onset horses must be rested, steamed with a teaspoonful of eucalyptus oil or turpentine, a rag dipped in Stockholm tar wrapped round the bit and left in the mouth for an hour or two at a time. A teaspoonful of saltpetre in drinking water three times a day. The disease is considered to be contagious, and is probably carried from horse to horse by flies, therefore isolation and destruction of flies should be attended to.

"T. R." had cow which was apparently well till day before death; then went stiff in legs and tongue protruded; condition was good.

Reply—Symptoms of dry bible; earlier ones not noticed. Prevention, bone meal and saltpetre 4-1.

"B. B." asks treatment for draught gelding which is losing condition, slobbers and feeds slowly although his teeth have been attended to; also rubs the hair off root of tail, though no lice are apparent.

Reply—Horses' teeth practically never require dental treatment which, as this case shows, is not followed by improvement. The mouth symptoms are caused by worms in the stomach, which live in the coats of that organ (*Habronema muscae*), and a heaped teaspoon of baking soda twice daily in the food for a month or so will probably relieve the symptoms. The tail symptoms arise most probably from whip worms in the hind gut, and they may be ejected by a clyster of a quart of warm milk containing four tablespoons

of turpentine. Otherwise they are caused by mange parasites, which would yield to a daily dressing of petrol one part and cheap oil five parts.

"G.," Parrakie, has cow suffering from stiffness and abnormal growth of hoof; she chews boards and bones. He seeks advice.

Reply—Early symptoms of dry bible; give in addition to lucerne a lick of saltpetre one part, bone meal three parts.

"A. F." had some young cows in good condition and in milk, they were taken suddenly ill with slaving, protruded tongue, rapid breathing, and after two days died. He asks cause.

Reply—As poison was unobtainable, the symptoms may have been those of gloss anthrax or tang, a form of blood infection which at times attacks cattle in the way described. Should there be further mishaps, drive a knife through the division of the nostrils so as to cut some of the blood vessels in it, and allow the beast to drink the blood as it flows; afterwards give 2ozs. of hyposulphite of soda in a pint of warm water and as a preventive let the other cows have a tablespoon of flowers of sulphur in the food once a day for a week or so.

"B. G. F." seeks treatment for foals whose mouths are full of white furred sores; thin shiny saliva constantly discharging. One died from similar affection.

Reply—The disease is thrush, a fungus affection of the mouth, which will probably yield to washing with a solution of boracic acid, a teaspoonful to a pint of warm water; also give twice daily on the tongue as much as will lie on a threepenny bit of grey powder (mercury and chalk). A dose of aloes would do the mare good, say a 5-dram ball after preparation.

"W. C. B." asks how to proceed with castrating horse suffering from scrotal hernia.

Reply—To prevent descent of the bowel in such a case it is necessary to make as small an incision as possible high up at the back of the scrotum and then proceed by the covered operation, that is, do not incise the peritoneal folds until the artery has been ligatured by absorbent gut; then excise the testicle and suture the peritoneal folds by similar gut. After treatment as usual, but large swelling is an advantage, and naturally occurs on account of situation of scrotal incision. An anæsthetic is a great help in such operations.

"A. J. R." asks treatment for horse, 7 years, which is in good condition but gets colic after a little work. Has been treated for sand, but is apparently free.

Reply—Probably a concretion in the colon. He would probably be relieved if kept on bran mash only for two days and then given a physic ball (6drs. aloes) and rested till scouring ceases. Afterwards give two teaspoons of this powder once a day in feed for a fortnight or so—Sulphur, 2ozs.; saltpetre, 2ozs.; nux vomica, 2ozs.; gentian, 2ozs.; linseed meal, 8ozs.; sugar, 8ozs.

"C. B.," Booborowie, has foal which hurt one of its eyes with a straw while sucking. There is a tiny puncture over the pupil, and a whitish film. It improved under Condy's fluid, but now there is a kind of bubble or wart where puncture was. He seeks advice.

Reply—The growth is granulation, due to ulceration of the cornea. Probably if a small pinch of dry boracic acid is blown into the eye twice a week a gradual recovery will set in, but this will take some weeks. It would be well to very lightly touch the spot with a caustic pencil. This, however, would involve the use of cocaine, and should only be done once.

"T. C.," Clarendon, has a cow which, after having been in milk for about three weeks (being fed with copra cake, pollard, and bran), refused her food, and became dicky on her legs.

Reply—Probably there is impaction of the rumen, and a pint of yeast given once a day will probably relieve in a day or two. Thistles, or any green bite, will be of use. Give once in warm water 1lb. Epsom salts,  $\frac{1}{2}$ oz. ginger, 1oz. sulphur.

"S. G. L." seeks advice concerning horses which after running on remains of drying up crop were shifted to spear grass and saltbush, and for last three weeks have been fed on chaff. They do not pick up as they should, and lie about a good deal.

Reply—Worms and sand are probably the trouble. Dose with milk and honey for the latter, and give two tablespoonfuls of Fowler's solution of arsenic, as so frequently prescribed, for the former.

"S. B.," Narrung, asks treatment for cows which, though in good condition, are dying of paralysis; one passes long, thin, wriggling worms about 1 $\frac{1}{2}$ in. in length in loose dung.

Reply—Yeast and similar treatment should be of use for the paralysis cases. Try half a cupful of benzine in a pint of raw linseed oil for the one with the worms. In case of death examine the lining of the paunch and fourth stomach (reed) carefully for very minute thread white worms.

"S. E. C." inquires treatment for draught mare 10 years, which formerly was very hotheaded mad rip, but about a year ago she lost energy. She feeds badly, has intermittent slight colic, soon tires, teeth in good order, bowels free (sometimes too much so), urine clear, very hollow about eyes, breath foul, lips hang loose.

Reply—The trouble is probably due to abscess in the stomach, caused by worms, which would not appear in the dung, and there are probably complications involving the liver and spleen, but there are no symptoms of enteritis. Mix the following:—Saltpetre, 4ozs.; sulphur, 4ozs.; sulphate of iron, 4ozs.; resin, 4ozs.; brown sugar, 2lbs; and give a tablespoonful once or twice a day in the food for a week or two.

"J. S. S.," Arno Bay, asks treatment for colt which when 2 months old was castrated, the cord being tied, and no emasculators or irons were used. Since the operation colt's purse has swollen, and running sores have appeared.

Reply—Ligature of the cord is not a good method for colts, which, so young, might simply be scraped like a pig. The hard swelling and running sores are due to infection by the germs of a fungus called botriomycosis, in its nature similar to actinomycosis. Treatment will be more successful if surgical, namely, cast the colt and remove all the hardened cord and sear; then dress with tincture of iodine, and repeat the dressing daily till healed. If it should break out again in a few months, then the colt should receive once a day in his food 1 dram of iodide of potassium for three weeks or so. The main thing is to thoroughly remove all affected cord.

"T. E. D. F." asks how long before a dose of oil or honey administered to a horse takes effect.

Reply—Oil generally takes from 12 to 15 hours to reach the colon, where sand accumulates. Honey alone about the same time; with milk it is acting in less than three hours.

"S. E." asks treatment for aged horse which has swelling along the gullet, not very pronounced; has difficulty in breathing, especially when drinking; will not eat even lucerne; is in no pain, but is rapidly wasting. He was drenched for sand but did not show any; dung fair, water very white.

Reply—Lung trouble; possibly some of the drench went the wrong way. Steam with a little eucalyptus oil, put Stockholm tar on bit and leave in mouth for an hour or two at a time. If absolutely off feed, give enemas twice a day of a quart of warm milk with three eggs beaten into it. Probable chance of recovery poor.

"M. L." had three horses on bush country at Dawson; they died in one night without preliminary symptoms, other horses there purged badly, while others on similar country did well. He asks probable cause of deaths.

Reply—The affected ones probably got hold of a poison weed such as *Euphorbium Drummondii*, or the bush feed was too irritant for their bowels. Fifteen drops tincture nux vomica twice a day for a week would help to clear the systems of those not so badly attacked.

"A. J." asks treatment for light horse which scours badly when driven, and is hard to keep in condition. He has had strangles badly twice, each time breaking out on chest.

Reply—The horse suffers from pyæmia, and there are probably abscesses on liver or spleen; he will not be a satisfactory patient to treat, but never let him drink for a couple of hours before going out; he may drink as often as he likes with the bit in his mouth on the road. Every Saturday night give a bran mash with a flat teaspoonful of calomel in it for a month or longer. Daily twice in food 10 drops of liq. hyd. perchlor B.P.

"A. J.," Spalding, asks if any injury is likely to result to livestock from being turned on to sorghum just flowering.

Reply—There is a certain amount of risk of stock blowing on sorghum; but if they are put on to it gradually with full bellies they will not come to harm. However, it is more economical to cut it and let it wilt for 12 or 24 hours. If an accident should occur, give a quarter of a pound of baking soda or hyposulphite of soda in a pound or two of molasses.

### IMPORTS AND EXPORTS OF PLANTS, FRUITS, ETC.

During the month of January, 1915, 1,512bush. of fresh fruits, 7,558bush. of bananas, 12,904 bags of potatoes, 271 bags of onions, and 7 packages of plants, trees, and bulbs were examined and admitted at Adelaide and Port Adelaide under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910. Four hundred and ninety bushels of bananas and 34bush. of plums (overripe) were destroyed. Under the Federal Commerce Act 50pkgs. of dried fruit and 41pkgs. of preserved fruit were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 50pkgs of currants; for India and East, 41pkgs. preserved fruit. Under the Federal Quarantine Act 848pkgs. of seeds, bulbs, plants, &c., were examined and admitted from oversea markets.

## ROSEWORTHY AGRICULTURAL COLLEGE.

## HARVEST REPORT, 1914.

By W. J. COLEBATCH, B.Sc. (Agric.), M.R.C.V.S., Principal Roseworthy  
Agricultural College.

## GENERAL REMARKS.

Five years ago when Professor Perkins went abroad, he left behind him the best fields of wheat that have been grown at the College Farm, and it fell to my lot to write an account of their harvest records. I refer to the year 1909, when the College average wheat yield exceeded 25bush. per acre.

By way of variation, I find on returning to the institution that the pendulum of fate has swung to the opposite end of its path, and that the task of preparing the annual harvest report has, in consequence, lost some of its congeniality. However, whilst it is natural to appreciate the inspiring influence of success in the farm fields, the interest engendered by close study of the experimental work in process at the College is intensified by the advent of novel climatic conditions.

The data brought together in a report covering harvest returns for the driest season on record must naturally constitute a basis for future comparisons, and in recognition of this fact every care has been taken to include all important observations and to retain the general scheme as laid down by my worthy predecessor. At the time of my arrival the fields were already beginning to respond to the stimulus of spring, and I had therefore to fall back on the experience of the Farm Superintendent and the Assistant Experimentalist in the preparation of those portions of the report dealing with the early history of the crops under review.

## THE WEATHER.

The climatic conditions experienced in the Roseworthy district in 1914 are unprecedented in the history of the College. For the first time since 1883, when the institution was established, the total number of inches of rain measured in any one season falls below double figures. During the 32 years for which rainfall records have been kept, the annual precipitation is found to average 17.2in., with a maximum fall of 27.60in., in 1890, and the minimum of 9.36in. in 1914. In Table I. are shown the monthly and annual rainfall records of the four driest seasons—1914, 1902, 1888, 1897—together with the means of the preceding 31 years.

TABLE I.—*Showing Rainfall in the Four Driest Seasons at Roseworthy College, comparatively with the Mean Fall during the period 1883-1913.*

| Month.          | 1897.   | 1888.   | 1902.   | 1914.   | Means,<br>1883-1913. |

| October .....   | 0.08    | 0.16    | 1.20    | 0.08    | 1.71                 |
| November .....  | 0.47    | 0.20    | 0.28    | 1.27    | 1.04                 |
| December .....  | 0.06    | 0.60    | 2.32    | 0.62    | 0.80                 |
| Totals .....    | 12.13   | 12.00   | 11.65   | 9.36    | 17.64                |

It will be observed that last season's total fall amounted to approximately one-half the mean annual fall for nearly a third of a century, and was rather more than 2½ in. below the previous minimum.

However, it is to the distribution rather than to the total fall that chief importance attaches in regard to cereal cropping, and Professor Perkins has recognised this point by drawing a distinction between "useful" rains and "total" rains. Where crops are grown under the bare fallow system the influence of rainfall on any particular crop cannot be properly comprehended without reference to the rain records for the year immediately preceding. Land fallowed at the right time usually receives sufficient rain to replenish the stores of moisture in the subsoil, and it is on this reserve supply that our crops have to depend in the later stages of growth during years of spring and summer droughts. Reference to the records indicates that the condition of the land as regards moisture at seeding time in the four driest years cited above varied considerably. The years 1888 and 1902 were preceded by seasons in which the rainfall exceeded the mean. In 1896 it amounted to nearly 15 in., and in 1913, 15.66 in. were registered. Adopting the classification of rains used in prior reports, we arrive at the following figures bearing on this question:—

TABLE II.—*Showing the Distribution of "Useful" Rains in the Years Immediately Preceding the Four Driest Seasons, together with the Corresponding Figures for 1914 and the Means of the previous 31 Years.*

|                           | 1896.   | 1887.   | 1901.   | 1913.   | 1914.   | Means,<br>1883-1913 |
|---------------------------|---------|---------|---------|---------|---------|---------------------|
|                           | Inches. | Inches. | Inches. | Inches. | Inches. | Inches.             |
| Seeding rains (April-May) | 4.50    | 2.93    | 3.25    | 0.62    | 2.32    | 3.45                |
| Winter rains (June-July)  | 4.38    | 5.88    | 5.90    | 0.91    | 1.77    | 4.45                |
| Spring rains (Aug.-Oct.). | 2.35    | 6.81    | 4.64    | 8.08    | 0.76    | 5.61                |
| Summer rains (November)   | 0.38    | 2.41    | 0.52    | 1.21    | 1.27    | 1.04                |
| Totals .....              | 11.61   | 18.03   | 14.31   | 10.82   | 6.12    | 14.55               |

Two important facts are revealed by this table. First, the shortage of winter rains in 1913, and second, the remarkable scarcity of sustaining showers in the spring of 1914. Not since 1911 have we experienced a series of drenching subsoil rains upon our fallow fields. It is true that rain was plentiful in the spring of 1913, but nearly 50 per cent. of the 8in. fell in October, and it is generally recognised that late spring rains are never so productive of benefit to the fallows as the winter soakings. Glancing again at the distribution of last year, it is clear that the season opened propitiously. There was a fine early ploughing rain in February, and a generous succession of timely seeding showers in April and May. The winter was marked by some severe frosts and an extraordinary absence of the usual downpours that characterise that season of the year. The winter rainfall did not amount to an average of an inch a month. Nevertheless, the wonderful capacity of cereals, and in particular of wheat, to respond promptly to every favorable stimulus, and to struggle through to harvest under adverse conditions would have inspired the hope for fair returns had the spring brought us even one good serviceable rain. It is seen, however, that such was not the case. From the 10th of September to the 16th of November—the period when growth and development are normally in full progress—the College gauge registered 18 points, and these were distributed over four separate days. There is no parallel for this depressing period in the history of the College Farm; but whilst many of the crops succumbed, it is consoling to reflect that a number of them withstood these extremes and yielded astonishingly well. This is an achievement which reflects great credit on the efforts of those responsible for the management of the farm fields and also on the system of seed selection introduced by the present Director of Agriculture for the specific purpose of fostering and developing the natural proclivities of our wheats to thrive under relatively dry and unfavorable conditions. It is truly remarkable to find wheats yielding up to 26½ bush. per acre in this district under a useful rainfall of 6.12in.—only 76 points of which fell during August, September, and October—and in a season following two distinctly dry years. Some of our crops were caught at blooming time by one or two hard frosts in September, and it is possible that in others the young ovules may have suffered through the intense heat of October, but I am not at all sure that the effects thus produced were not more beneficial than noxious in view of the scarcity of reserve soil moisture. There were no blizzards or blighting hot winds, and the crops did not suffer appreciably from either rust or takeall. At one stage it appeared that the wheat or grass “mildew” (*Orysiphe graminis*) which was observed over large areas both here and in neighboring districts was going to do considerable harm to the wheat crops, and although somewhat alarmed at first, I am now of opinion that had growing conditions prevailed in September and October, the crops would have rapidly recovered their vigor without treatment of any kind.

One result of the drought was to bring about an early harvest. We began hay cutting in the middle of September, and before the end of November the whole of the produce was under cover and the grain stacked ready for grading.

### HAY CROPS.

Athay-making time in 1913 there was a fair "carry over" from the previous year, but by October, 1914, the shed was empty and we were faced with the prospects of a hay harvest of 150 tons to 160 tons and an average monthly consumption of 25 tons to 30 tons. It was obvious that all ideas of ensiling portion of the crop would have to be abandoned, and as a consequence that the dairy herd, thus deprived of 120 tons to 150 tons of summer fodder, would be bound to make heavier demands than usual on the hay supply. Even after making optimistic estimates of the grain yield in order to secure as large a hay area as possible, it was not anticipated that the College fields would return more than half the total amount required to satisfy our needs. It need hardly be said that every care was taken to save all the hay, straw, cavings, and cocky chaff available to us. Relatively large areas were so poorly grown that the mower and rake had to be employed in place of the binder, and upwards of 50 acres had to be grazed off. Areas originally intended for hay were sown in Grainger's B, No. 16, Nottle's A and 5A. These amounted in all to about 100 acres, the idea being to cut into the wheat paddocks as far as circumstances demanded in order to provide a full complement of hay for the coming year. Only about 60 acres of the original hay area produced a mowable crop, and consequently all that could be made available in Nottle's B and Grainger's A had to be cut in addition. Even then we were not able to stack more than 180 tons at the steading, and the supply had to be augmented by outside purchases. The quality of the hay is known to depend on the proportion of heads to straw and flag, and since the crops were short, it follows that the food value of the 1914 produce is relatively high.

### GRAINGER'S B.

Previous history—1908, bare fallow; 1909, wheat and oats; 1910, bare fallow; 1911, wheat and oats; 1912, pasture; 1913, bare fallow; 1914, wheat and oats.

The total area of this field is approximately 35 acres, and of this 15.652 acres, under King's White (selection 5), were harvested for hay. The remainder carried Calcutta oats, which was used to top off the lambs. The fallow was cultivated in March, and a month later received a dressing of 133lbs. of superphosphate per acre. The field was then cultivated, and between the 25th and 27th of April Calcutta oats at the rate of 104lbs. per acre were drilled in over 20 acres. The balance of the paddock was then

sown to King's White (5th selection) at 2bush. to the acre. At the time of seeding the manurial dressing was raised to a total quantity of 2cwts. per acre. A stroke of the harrows concluded seeding operations.

The oats failed as a hay crop, and were turned over to the lambs on the 21st of September. However, the wheat grew to an average height of 2ft. 6in. and ripened off about the middle of September. It was cut a little on the green side for the reason that the birds began to strip the heads. The yield came out at 23½ tons, or an average per acre of 1 ton 9cwts. 79lbs. This was a long way the highest hay yield on the farm this season, and is more than double the average return over the whole area. I am informed that the success of this crop is due in large measure to the banking up of the February flood in the middle of the field, the flood waters becoming imprisoned remained to saturate the soil to an extent that interfered with the March cultivation.

#### FIELD No. 16.

Past history—1899, bare fallow ; 1900, wheat and oats ; 1901, bare fallow ; 1902, wheat ; 1903, pasture ; 1904, melons and pumpkins ; 1905, barley and rye ; 1906, pasture ; 1907, pasture ; 1908, bare fallow ; 1909, wheat ; 1910, barley ; 1911, pasture ; 1912, pasture ; 1913, sorghum ; 1914, barley and wheat.

It will be noticed that this field carried a crop of sorghum in the summer of 1913, and it is not surprising, therefore, in view of the known influence of the summer crop on the succeeding cereal in the district that the barley and wheat should both have failed in a season of such phenomenally low rainfall. The stubbles were disced up at the end of March, and worked down fine with roller and harrows. One-half of the manure (1cwt. 36/38 superphosphate) was applied on the 21st of April, and the drill was immediately followed by the cultivator. Between the 7th and 9th of May 21 acres were sown with King's Red (6th selection), 114lbs. per acre, and the second hundred-weight of manure. The seed germinated very well, but except in a few crab holes on the land recently cleared, the crop never grew more than 8in. or 9in. high, and eventually it shrivelled off whilst the heads were still shooting. In order to gain some return for the labor and outlay expended, ewes and lambs were turned in on August 29th, and the field was subsequently treated as pasture.

#### NOTTLE'S A.

Previous history—1897, bare fallow ; 1898, wheat ; 1899, wheat ; 1900, bare fallow ; 1901, wheat ; 1902, pasture ; 1903, bare fallow ; 1904, wheat ; 1905, bare fallow ; 1906, wheat and barley ; 1907, pasture ; 1908, bare fallow ; 1909, wheat, oats, and lucerne ; 1910, pasture ; 1911, pasture ; 1912, pasture ; 1913, bare fallow ; 1914, wheat, oats, and barley.

There were between 54 and 55 acres of crop in this field. Only 28 acres were actually sown for hay, the remainder being occupied by various seed

plots of wheat, barley, and oats. Eventually, however, it was decided to include some of the better grown plots in the hay area and to exclude about 5 acres of the hay mixture which was too short to handle. The land was broken with the disc plough and cultivator in January, rolled and harrowed immediately after, and cultivated in March. Soon after the middle of April superphosphate at the rate of 128lbs. per acre was drilled in on the area reserved for hay. A week later 5½ acres were drilled in with 2bush. per acre of a mixture of Queen Fan (60lbs.) and Calcutta oats (40lbs.) per acre. The whole block, 28 acres, was next dressed with 96lbs. of superphosphate per acre, and the unsown portion was then broadcasted with 110lbs. per acre of a mixture containing 70lbs. of Marshall's No. 3A and 3B (3rd and 4th selections) and 40lbs. of Calcutta oats.

The drilled area yielded better than the broadcasted, but the returns were so out of proportion to the quality of the land under normal conditions that very little importance can be attached to the comparison. The five-acre block that failed formed a part of the broadcasted section. The total area harvested for hay was 44.429 acres, and the acre yield amounted to 13cwts. 55lbs.

#### FIELD NO. 5A.

Previous history—1897, bare fallow; 1898, wheat; 1899, wheat; 1900, bare fallow; 1901, wheat and oats; 1902, pasture; 1903, bare fallow; 1904, wheat; 1905, bare fallow; 1906, wheat and oats; 1907, bare fallow (limed); 1908, wheat, oats, and barley; 1909, wheat, oats, barley, and lucerne; 1910, pasture; 1911, pasture; 1912, pasture; 1913, bare fallow; 1914, wheat, oats, and barley.

Between New Year's Day and seeding time the fallows were cultivated three times and harrowed once. On April 23rd and 24th 15.241 acres of Scotch Grey oats (70lbs. per acre) and 2cwts. first grade superphosphate were drilled in at the western end. The drill was then kept going till the whole field was sown. Eleven different varieties of wheats were sown for seed, but had to be sacrificed in the interests of the hay harvest. The Scotch Grey oats obtained a splendid start, and if they had received a reasonable amount of encouragement in the spring it is probable they would have given a higher return than the general hay average of the farm for the preceding 10 years. As soon as an opportunity arises of securing good seed at a reasonable price, the intention is to give this variety of oat a more extended trial. There is little of interest to remark about the various wheat plots, unless it be to state that they were all too short to bind into satisfactory sheaves. The whole of the oaten block had to be mown, raked into windrows, and cocked after the manner of meadow hay, which, of course, entailed considerable labor and expense. The hay area in this field totalled 39.222 acres, and the return per acre worked out at 13cwts. 98lbs.

Two important facts are revealed by this table. First, the shortage of winter rains in 1913, and second, the remarkable scarcity of sustaining showers in the spring of 1914. Not since 1911 have we experienced a series of drenching subsoil rains upon our fallow fields. It is true that rain was plentiful in the spring of 1913, but nearly 50 per cent. of the 8in. fell in October, and it is generally recognised that late spring rains are never so productive of benefit to the fallows as the winter soakings. Glancing again at the distribution of last year, it is clear that the season opened propitiously. There was a fine early ploughing rain in February, and a generous succession of timely seeding showers in April and May. The winter was marked by some severe frosts and an extraordinary absence of the usual downpours that characterise that season of the year. The winter rainfall did not amount to an average of an inch a month. Nevertheless, the wonderful capacity of cereals, and in particular of wheat, to respond promptly to every favorable stimulus, and to struggle through to harvest under adverse conditions would have inspired the hope for fair returns had the spring brought us even one good serviceable rain. It is seen, however, that such was not the case. From the 10th of September to the 16th of November—the period when growth and development are normally in full progress—the College gauge registered 18 points, and these were distributed over four separate days. There is no parallel for this depressing period in the history of the College Farm; but whilst many of the crops succumbed, it is consoling to reflect that a number of them withstood these extremes and yielded astonishingly well. This is an achievement which reflects great credit on the efforts of those responsible for the management of the farm fields and also on the system of seed selection introduced by the present Director of Agriculture for the specific purpose of fostering and developing the natural proclivities of our wheats to thrive under relatively dry and unfavorable conditions. It is truly remarkable to find wheats yielding up to 26½ bush. per acre in this district under a useful rainfall of 6.12in.—only 76 points of which fell during August, September, and October—and in a season following two distinctly dry years. Some of our crops were caught at blooming time by one or two hard frosts in September, and it is possible that in others the young ovules may have suffered through the intense heat of October, but I am not at all sure that the effects thus produced were not more beneficial than noxious in view of the scarcity of reserve soil moisture. There were no blizzards or blighting hot winds, and the crops did not suffer appreciably from either rust or takeall. At one stage it appeared that the wheat or grass “mildew” (*Orysiphe graminis*) which was observed over large areas both here and in neighboring districts was going to do considerable harm to the wheat crops, and although somewhat alarmed at first, I am now of opinion that had growing conditions prevailed in September and October, the crops would have rapidly recovered their vigor without treatment of any kind.

One result of the drought was to bring about an early harvest. We began hay cutting in the middle of September, and before the end of November the whole of the produce was under cover and the grain stacked ready for grading.

### HAY CROPS.

At hay-making time in 1913 there was a fair "carry over" from the previous year, but by October, 1914, the shed was empty and we were faced with the prospects of a hay harvest of 150 tons to 160 tons and an average monthly consumption of 25 tons to 30 tons. It was obvious that all ideas of ensiling portion of the crop would have to be abandoned, and as a consequence that the dairy herd, thus deprived of 120 tons to 150 tons of summer fodder, would be bound to make heavier demands than usual on the hay supply. Even after making optimistic estimates of the grain yield in order to secure as large a hay area as possible, it was not anticipated that the College fields would return more than half the total amount required to satisfy our needs. It need hardly be said that every care was taken to save all the hay, straw, cavings, and cocky chaff available to us. Relatively large areas were so poorly grown that the mower and rake had to be employed in place of the binder, and upwards of 50 acres had to be grazed off. Areas originally intended for hay were sown in Grainger's B, No. 16, Nottle's A and 5A. These amounted in all to about 100 acres, the idea being to cut into the wheat paddocks as far as circumstances demanded in order to provide a full complement of hay for the coming year. Only about 60 acres of the original hay area produced a mowable crop, and consequently all that could be made available in Nottle's B and Grainger's A had to be cut in addition. Even then we were not able to stack more than 180 tons at the steading, and the supply had to be augmented by outside purchases. The quality of the hay is known to depend on the proportion of heads to straw and flag, and since the crops were short, it follows that the food value of the 1914 produce is relatively high.

### GRAINGER'S B.

Previous history—1908, bare fallow ; 1909, wheat and oats ; 1910, bare fallow ; 1911, wheat and oats ; 1912, pasture ; 1913, bare fallow ; 1914, wheat and oats.

The total area of this field is approximately 35 acres, and of this 15.652 acres, under King's White (selection 5), were harvested for hay. The remainder carried Calcutta oats, which was used to top off the lambs. The fallow was cultivated in March, and a month later received a dressing of 133lbs. of superphosphate per acre. The field was then cultivated, and between the 25th and 27th of April Calcutta oats at the rate of 104lbs. per acre were drilled in over 20 acres. The balance of the paddock was then

sown to King's White (5th selection) at 2bush. to the acre. At the time of seeding the manurial dressing was raised to a total quantity of 2cwts. per acre. A stroke of the harrows concluded seeding operations.

The oats failed as a hay crop, and were turned over to the lambs on the 21st of September. However, the wheat grew to an average height of 2ft. 6in. and ripened off about the middle of September. It was cut a little on the green side for the reason that the birds began to strip the heads. The yield came out at 23½ tons, or an average per acre of 1 ton 9cwts. 79lbs. This was a long way the highest hay yield on the farm this season, and is more than double the average return over the whole area. I am informed that the success of this crop is due in large measure to the banking up of the February flood in the middle of the field, the flood waters becoming imprisoned remained to saturate the soil to an extent that interfered with the March cultivation.

#### FIELD No. 16.

Past history—1899, bare fallow ; 1900, wheat and oats ; 1901, bare fallow ; 1902, wheat ; 1903, pasture ; 1904, melons and pumpkins ; 1905, barley and rye ; 1906, pasture ; 1907, pasture ; 1908, bare fallow ; 1909, wheat ; 1910, barley ; 1911, pasture ; 1912, pasture ; 1913, sorghum ; 1914, barley and wheat.

It will be noticed that this field carried a crop of sorghum in the summer of 1913, and it is not surprising, therefore, in view of the known influence of the summer crop on the succeeding cereal in the district that the barley and wheat should both have failed in a season of such phenomenally low rainfall. The stubbles were disced up at the end of March, and worked down fine with roller and harrows. One-half of the manure (1cwt. 36/38 superphosphate) was applied on the 21st of April, and the drill was immediately followed by the cultivator. Between the 7th and 9th of May 21 acres were sown with King's Red (6th selection), 114lbs. per acre, and the second hundred-weight of manure. The seed germinated very well, but except in a few crab holes on the land recently cleared, the crop never grew more than 8in. or 9in. high, and eventually it shrivelled off whilst the heads were still shooting. In order to gain some return for the labor and outlay expended, ewes and lambs were turned in on August 29th, and the field was subsequently treated as pasture.

#### NOTTLE'S A.

Previous history—1897, bare fallow ; 1898, wheat ; 1899, wheat ; 1900, bare fallow ; 1901, wheat ; 1902, pasture ; 1903, bare fallow ; 1904, wheat ; 1905, bare fallow ; 1906, wheat and barley ; 1907, pasture ; 1908, bare fallow ; 1909, wheat, oats, and lucerne ; 1910, pasture ; 1911, pasture ; 1912, pasture ; 1913, bare fallow ; 1914, wheat, oats, and barley.

There were between 54 and 55 acres of crop in this field. Only 28 acres were actually sown for hay, the remainder being occupied by various seed

plots of wheat, barley, and oats. Eventually, however, it was decided to include some of the better grown plots in the hay area and to exclude about 5 acres of the hay mixture which was too short to handle. The land was broken with the disc plough and cultivator in January, rolled and harrowed immediately after, and cultivated in March. The whole of the oaten block had to be mown, raked into windrows, and cocked after the manner of meadow hay, which, of course, entailed considerable labor and expense. The hay area in this field totalled 39.222 acres, and the return per acre worked out at 13cwts. 98lbs.

## NOTTLE'S B.

This is one of the two fields that were not intended for hay unless circumstances proved adverse. Up to the year 1909 it formed one paddock with Nottle's A, and consequently has the same history up to that date. In 1910 it was bare fallowed, in 1911 it carried wheat, oats, and beans, and in the following year wheat, oats, and barley. The stubble was then fallowed up in 1913, and sown to wheat last autumn. Of the 156 acres included in its boundaries, no less than 118.344 had to be cut for hay. The acre yield (12cwts. 107lbs.) was certainly very low, but it must be noted that the crop was not sown for hay, that the block included a number of poor hay varieties, such as Federation, Comeback, and Jonathan, and further that the better-grown selections were in every instance reserved for seed. The fallow was disc cultivated in January, scarified in April, and again in May in front of the drill. Seeding extended from May 22nd to June 6th, and the whole field received 2cwts. of superphosphate to the acre.

## GRAINGER'S A.

This field is laid out into two series of 4-acre plots, designed to ascertain the relative merits of various methods of preparatory cultivation for wheat in this district. The plots were surveyed off three years ago, the first harvest being obtained in 1912. The general scheme will become intelligible on reference to the following summary of tillage operations in respect of each pair of plots.

## [Plan of Experiment.]

*Early Fallow.*—Plot 1 (A and B) ploughed 7in. deep and immediately rolled with heavy roller. Cross cultivated before September 1 and harrowed immediately afterwards. Cultivated and harrowed subsequently as often as surface crust or weeds rendered it necessary. Plot 2 (A and B) ploughed 7in. deep and immediately harrowed. Cultivated before September 1st, and subsequently as often as found necessary. Plot 3 (A and B) ploughed 7in. deep and cultivated three times in the course of the season. Harrowed at seeding time. Plot 4 (A and B) ploughed 7in. deep. Cross skim ploughed before September 1st and cultivated subsequently as often as necessary.

*Late Fallow.*—Plot 5 (A and B) ploughed 7in. deep after 1st of September, and heavily rolled same day as ploughing. Cultivated not later than three weeks after rolling, and if possible after rain. Rolled, cultivated or harrowed, according to the condition of the tilth. Thorough tillage throughout. Plot 6 (A and B) ploughed 4in. deep after 1st of September. Cultivated after fall of rain, and subsequently as often as necessary.

In the appended table special notes pertaining to the treatment of the plots cropped in 1914 are included, together with the season's results and the mean returns for the period 1912/14. All the plots were sown between the 6th and 9th of May with Queen Fan (selection 1), 90lbs. per acre, and 36/38 mineral superphosphate, 2cwts. per acre.

TABLE III.—*Showing Results obtained from Grainger's Cultivation Plots, 1912-14.*

| Plot. | Treatment of 1913-14 Fallows.                                                                                                                                                             | Yield<br>per Acre.<br>Means,<br>1912-13.<br>Bush. lbs. | Produce per Acre. |    |    |                    |    |     |

In one sense it is regrettable that the extremity of the circumstances compelled us to turn these crops into hay, but our disappointment is tempered by the knowledge that in 1914 an accidental factor has upset what may be regarded as the normal relation of early and late fallows in dry years. Unfortunately there is a depression running across the field, and in flood times the water gravitates into this hollow and submerges the greater part of plot No. 5A. This is precisely what occurred in February last, and in consequence we find the spring-ploughed fallow giving higher returns of total produce than the early fallows in the driest season on record.

However, this kind of misfortune is being constantly met with in experimental field work, and whilst the proper relationship of the plots may be temporarily disarranged, these occasional elements of disturbance are gradually counteracted by contrary influences, and the effects are ultimately obliterated by the steady accumulation of additional data. Referring back to the table, it will be observed that the figures for the early fallows are

fairly uniform, there being a slight advantage in favor of the rolled plot, both in 1914 and in the average return. Contrary to last year's experience, plot No. 3, which receives the least cultivation, has come out slightly ahead of No. 2, but it is improbable that this relation will be maintained in future years. As regards the late fallows, plot No. 5A has already been commented upon, and the figures for the shallow spring-ploughed plot are separated from the rest of the series by so wide a margin in both the seasonal and mean yield columns that no further doubts should exist as to the disadvantage of pursuing such a system in dry years. To what extent the discrepancy will disappear after a cycle of wet seasons has elapsed still remains to be worked out. The total area harvested in this field was 27·255 acres, and the yield per acre 16cwt. 72lbs.

#### RELATION BETWEEN THE AMOUNT OF HAY CUT AND BINDER TWINE USED.

Following the plan adopted in other years, careful records were kept of the amount of twine used in each field, and the average figures for the hay harvest of 1914 are given in the appended table, together with the corresponding figures for the three immediately preceding years. It will be seen that our results, which now extend over four years, with an average cut of over 250 tons per annum, bear out the generally accepted ratio of one ball of twine to about 2 tons of hay.

TABLE IV.—*Showing the relation between a Ball of Binder Twine and the amount of Hay cut, 1911 to 1914.*

| Year.       | Area.<br>Acres. | Yield<br>per Acre. |       |      | Twine Used.<br>Balls. | Hay Cut<br>per Ball. |       |      |

| 1911 .....  | 200·100         | 1                  | 8     | 6    | 120½                  | 2                    | 6     | 65   |
| 1912 .....  | 237·223         | 1                  | 14    | 90   | 200½                  | 2                    | 0     | 54   |
| 1913 .....  | 228·909         | 0                  | 16    | 6    | 108                   | 1                    | 14    | 3    |
| 1914 .....  | 232·406         | 0                  | 14    | 78   | 85                    | 2                    | 0     | 17   |
| Means ..... | —               | 1                  | 3     | 45   | —                     | 2                    | 0     | 35   |

#### THE GENERAL AVERAGE HAY YIELD, 1914.

Additional upon the hay crops already enumerated, there is included in the total figures a small load amounting to 1 ton 17cwt. 31lbs., cut from 2·745 acres made up of headlands and plot divisions in Ebsary's C. In reading the figures in the appended summary of the hay harvest for last year, it must be understood that they do not represent average returns from areas sown under proper hay-growing conditions, but are the mean figures for the total acreage harvested and are, therefore, inclusive of headlands, experimental areas and, in the case of the present year, all cereal crops that were unlikely to yield much grain. In fine, the policy has been to sacrifice yield per acre for the sake of securing the maximum total quantity.

TABLE V.—*Showing Average Hay Yields on the College Farm, 1904 to 1914.*

| Season.                            | Rainfall.            |                   | Area. | Acres. | Average         |       |      |

## BARLEY CROPS.

Over 200 acres were sown with Cape barley, but only 12.847 were harvested for grain. The whole of Flett's (174 acres), the entire barley area in No. 16 (38 acres), four acres in the Permanent Experiment plots, and approximately an acre in Nottle's A were given over to grazing before the end of August. The crop in Flett's followed the wheat stubble and went in early in May at the rate of 2bush. per acre. This heavy seeding was intended to assist the young crop to crowd out the charlock with which this field is infested. As it happened the season was a most unsuitable one for this experiment; but even if the field had been sown with 60lbs. or 70lbs. instead of 100lbs. it is most unlikely that the crop would have paid for harvesting. In field No. 16 the barley succeeded a crop of sorghum and was not drilled in till the end of May. It had, therefore, even less chance of success than the larger area, and it was decided to abandon it as a crop three weeks before a similar decision was arrived at in the case of Flett's. The 12.478 acres that were stripped occurred in fields No. 5A and No. 6B and the Permanent Experiment Field. Really speaking, only 3 out of the 22 plots concerned were worth harvesting; but as many of the varieties were imported from abroad an effort was made to save seed wherever possible. The effect, of course, will be to depreciate the average yield, since the mean return for 1914 works out at less than 7 per cent. of the average acre yield for the previous decade. The failure of barley, however, in 1914, furnishes no criterion of its importance in this district, since our own records serve to show that in nine out of the last 11 years the crops have been decidedly profitable, and even after this year's average of 2bush. 26lbs. is included the mean return for the period 1904-1914 is within a few pounds of 30bush. per acre. It is an unfortunate coincidence that in the most disastrous barley year we should have had no less than 235 acres, or nearly double the previous highest barley areas, under this crop.

In those abscesses which are difficult to heal, whose edges are round and thickened, a stimulant of some kind will be required. Arsenical sheep dip, such as Cooper's, applied to the edge of the wound once a day or less frequently will bring about the desired result.

In order to lessen the cough and ease the discharge, a rag dipped in Stockholm tar may be wrapped round the bit and left in the horse's mouth for an hour or more at a time. This will cause a free flow of saliva, and the soluble properties of the tar will be taken into the stomach and absorbed by the system. The volatile substances, or qualities, will be breathed directly in the windpipe and air tubes. This may be done once or twice a day.

When the nostrils are badly blocked, steaming may be advisable; but, as a horse generally expects to find feed at the bottom of a nosebag, it is better to cover the surface of the material used to hold the boiling water with a bit of blanket, through which the steam will rise, but will not scald the animal's nose as it would if he dipped it into the wet chaff or bran. Drugs may be used with the steaming—a teaspoonful of any coal tar disinfectant, a like quantity of oil of eucalyptus or turpentine (larger quantities should not be given). When recovery is setting in sulphate of quinine may be given with the feed, or may be mixed with molasses. A dose of quinine is roughly a teaspoonful, from 30 to 40 grains, which may be given twice a day. Feeding from the ground is most convenient, as, in this position the discharges are easily got rid of from the throat and nose.

Another type of breathing disease which is more likely to affect adult horses is commonly spoken of as "influenza," although this name means nothing at all. The symptoms are somewhat as follows:—Horses working in the team are noticed to be off color, sweat too freely, perhaps now and again cough, and after returning to the stable the sweat does not dry. They do not care about their feed. The next morning when they are being tackled up they are noticed to turn stiffly. Some people will say the soreness is across the loins, others will say that it is in the chest; as a matter of fact it is generally in both places, and sometimes causes so much pain that the animal will groan, especially if roughly handled.

In other cases swelling of the fetlock may be noticed, extending part way up the leg, and there will be discharge from the nose, either clear or snotty, with a deep cough in some cases. When such symptoms are noticed it is necessary to give the horse a spell of 24 hours, and a dose or two of saltpetre (a teaspoonful) in warm bran mash will pretty well put things right; but three or four hours' work will often end in acute congestion or inflammation of the lungs. The swelling of the legs may be very pronounced in the higher parts, under the belly, the sheath, or udder, the breast, and up the neck, and is often the first symptom to be noticed. It is really a good sign. It means that Nature is side-tracking poison which the kidneys and lungs cannot work out of the

system, as they are deposited in the loose tissues between the gland and the muscles, where, beyond causing a stiffness, they cannot do much harm, and will gradually be absorbed; but work must not be given. When Nature is thus throwing out poison the breathing organs are in an irritable condition, and any strain upon them may result in acute disease.

With regard to medicines, Stockholm tar on the bit is, perhaps, the most useful. Photographer's hypo. in 1oz. doses, or Epsom salts, in similar quantities, given two or three times a day will keep down the temperature and clear the blood. Saltpetre is also good. A dose of ammonia, or arsenic, such as a tablespoonful dose of "Fowler's solution," or 10 to 20 drops of tincture of arsenic will all be useful when the acute fever has been allayed. For the fever 10 to 20 drops of tincture of aconite may be given every three or four hours. The puffiness and swelling should not be lanced, as other germs may enter from the air or bed, and thereby cause abscesses to form. The swelling may, however, be well and frequently bathed with hot water, taking care that they are thoroughly dried off afterwards. Acute complications, such as inflammation of the lungs, are shown by the rapid wasting of the horse, a very high temperature, dilated nostrils, and the labored breathing, the pleuritic ridge, and rapid weakening of the beast. In the horse they are practically incurable, but in those cases where the constitution is good, and the struggle lasts long, even up to 10 grains of iodide of arsenic, mixed with twice its weight of sugar of milk, may be put upon the tongue twice a day, often with good results.

It will have been noticed that nothing has been mentioned with regard to "drenches." These should never be given in breathing diseases, because if any goes the wrong way it will quickly bring about inflammation, and any medicines required can be given in other forms.

Haymaking

## PEACH PRUNING.

### A NEW SYSTEM.

The article printed below is taken from *The Pacific Rural Press* of October 24th. The new system of pruning peach trees described approximates to a method now being tried by some fruitgrowers on the Murray, and Mr. George Quinn (Horticultural Instructor) has been experimenting on the same lines

Six-year-old Peach grown under irrigation. Pruned on new system adopted by Mr. Quinn.

in one of the orchards under his control. From results to date, Mr. Quinn is of opinion that the new method should prove satisfactory at places where vigorous growth, such as can be obtained by irrigation, can be maintained year after year. On the other hand, where the system has been tried without the trees having been irrigated, and in a season such as the present, the results, so far, have been disappointing. The article reads :—

Whether to prune peaches now or later, whether to prune as our fathers did, or as the Japanese of Placer county do, or as certain observant present-day successful growers are doing, must be decided before the election. Not because peach pruning has any political aspect, but because November will be a good time to do it if you have not pruned them as soon as the crop was off. Many of the leaves will still be on to help distinguish dead wood, and the fall rains will not have softened the ground too much. But bear in mind that pruning this November will have the same effect on the tree as pruning any time in winter.

Ed. Ames, a successful fruit-grower of Placer county, whose fruit is highly commended by the Newcastle fruit shippers, has a system for his 40 acres of peaches which appears reasonable, though new to most of us. It is a

Fourteen-year-old Peach. 7½ft. high, 14ft. spread. Pruned as described in article.

system which he claims produces maximum crops because it uses practically all of the energy of the tree for fruit production instead of wasting it on new growth, which would have to be constantly cut back.

Briefly, his method is this—A new shoot grows 1ft. to 3ft. this year. Do not cut it back next year, but let it grow. There will be a few peaches on it and a great many strong buds will develop to set and mature a crop the following year. After that crop is off, cut off the whole shoot back to the main branch. Other buds will grow from about the same place and below it on the big limbs to go through the same cycle. While this shoot is bearing its heavy crop, others will be growing and setting fruit buds for the year when the first-mentioned one has been cut off. The philosophy of it is this—When you cut off a new shoot several others start next season near the cut, and draw all the sap from the buds below. They are stunted and probably killed. The several new shoots use a lot of sap that ought to go to fruit, for it is well known that the cutting back stimulates undue wood growth. You will have your trouble of cutting back year after year; and as time goes on, you build the tree higher and higher out of the reach of fruit pickers. It forces the leaves and fruit out to the ends of the limbs, for the new growth at the end takes the sap from buds inside. If a big limb dies on the south or west side, the whole inside of the tree is exposed to sunburn, which is the cause of more peach trouble than anything. If the new shoot had been cut back last year, it would have borne some fruit on the stub while sending out the new wood. Then the fruit spurs would have died and only the new wood could bear this year, for it alone would have set fruit buds in summer for this year's crop.

With Mr. Ames' system, after a tree is large as convenient to prune and pick from, the fruit is forced out all along the limbs where it can be most securely held up and most thoroughly nourished. The tree does not grow appreciably higher, there is very little waste wood growth, for the shoots unpruned grow only a very few inches and that few inches is good for the production of necessary leaves. If a limb dies, the rest of the big limbs are protected from sunburn and consequent borers by the foliage among the fruit. There will be a maximum crop of fruit, more than the tree could stand otherwise, and it will be as large sized as that of Mr. Ames, so that it takes fancy prices on market. If the tree seems too prolific, take out more wood—always at its junction with the limb from which it springs. The tree is kept open enough always to supply light to the inner fruit spurs, but enough new wood is left to protect it from sunburn.

New spurs are constantly growing among the bearing ones, so that the old limbs continue to bear. Should the new spurs get a little too thin, or the tree seem to need more leaves, a few shoots may be cut back for the sole purpose of providing new wood.

This system is approved by Deputy Horticultural Commissioner F. C. Brosius, of Sacramento county, who has tried a similar system in Eldorado county with excellent results. It makes the limbs self-supporting, and removes the need of props, which would be in the way.

A similar system is to be used this November on the canning and drying peaches of Landan and Clough of Atwater. Their Tuscan and Elbertas are eight years old, the Phillips are seven. It is only two years that the present manager has had control, so he will work out the system on trees formed the other way.

His object in pruning will be to regulate the amount of fruit by snipping off entire fruit spurs and short new growth till they are just thin enough so that all the fruit that will set will not break the limb. More will be left on limbs that hang downward without having to make a short bend, for such can hold more fruit than those that project upward at a stiff angle. More will be left on strong, stocky limbs than on slender ones.

There is little danger that leaving just the right number of spurs will cause a light crop by fruit not setting, for the spurs will be so strong that if pollen drops on the flowers at all, fruit will almost invariably set and grow as well as climate and pests will allow. And if the fruit should be a bit thin, it will be larger to make up for it; and the canners jump at big fruit.

The longest new growth will be cut back to shape the tree; shorter new growth will be left alone as much as possible. The vigorous wood that will come from the cut shoots may be cut off entirely in summer to induce setting of fruit spurs along the old wood.

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board was held on Wednesday, February 10th. There were present Mr. G. R. Laffer, M.P. (in the chair), Director of Agriculture (Prof. A. J. Perkins), Principal Roseworthy Agricultural College (Mr. W. J. Colebatch, B.Sc. (Agric.), M.R.C.V.S.), Chief Inspector of Stock (Mr. T. H. Williams), Messrs. C. J. Valentine, C. H. Tuckwell, J. Miller, G. Jeffrey, C. E. Birks, F. Coleman, A. M. Dawkins, and the Acting Secretary (Mr. H. J. Finnis).

*Imported Seed Wheat.*—The following resolution from the Strathalbyn Branch of the Bureau was tabled:—"That it be a request to the Board that if grain is imported for seed stringent regulations should be made and enforced in order that injurious weeds and noxious pests may be guarded against." Professor Perkins pointed out that none of the imported wheat would be used for seed purposes, but it would all go through the mills and be converted into flour and offal. At the instance of Mr. Dawkins, it was decided to notify the Branch accordingly.

*The Chapman Sack.*—The Strathalbyn Branch also passed a resolution vigorously protesting against "limiting the quantity of grain placed in a Chapman cornsack to 200lbs." In support of its attitude it cited some comments made recently by Mr. E. A. Badcock, of the Farmers' Co-operative Union. These were to the effect that merchants had been notified that an

odd bag or two had been received on the wharf weighing more than 200lbs. ; that it was contrary to the law to ship such bags ; and that the violation of the law involved liability to a heavy fine as well as to imprisonment. There was no question that the railway officials had been lenient in the matter, but apparently the Customs authorities had their instructions that sacks containing more than 200lbs. must not be exported. In consequence of the rigidity and drastic nature of the Act, it had been found necessary in numerous cases to open bags and take out some of the grain. One member thought that the Act really offered an inducement to farmers not to trouble to clean their wheat. A motion was carried, "That the attention of the Minister for Customs be called to the subject, and that he be informed that the Board considers that so long as Chapman sacks are used the law should be satisfied."

*Fixation of Prices by Government.*—A communication from the Crystal Brook Branch recommended that in view of the fact that the farmers proposed this year to put in as large an area of wheat as possible, it was desirable that the Government should be asked to give an assurance that it would not fix the price of grain, and that the various Branches of the Bureau should, by circular, be invited to support the request. During the discussion which ensued, Professor Perkins contended, and his opinion was indorsed by others, that the move was altogether premature. It was hoped that the season would be successful in every respect. It was determined that the Board could not see its way to support the resolution from the Branch.

*Clean Seed Wheat.*—Mr. F. Coleman drew attention to the prevalence of smut in wheat being used for seed this year, and suggested that the necessity for care in pickling should be brought under the notice of farmers. The Board concurred.

*Lower Northern Conference.*—On the motion of Mr. Dawkins, seconded by Mr. Coleman, it was decided to accept the invitation to hold the Conference of Lower Northern Branches at Riverton during the second week in March.

*New Branch.*—Approval was given to the formation of a new Branch at Yeelanna, with the following gentlemen as members:—W. Proctor, H. Roediger, H. Glover, R. Brown, J. Carey, — Smith, — Smith, — Weymiss, — Weymiss, B. Havelburg, H. Proctor, J. Cronin, — Havelburg, — Havelburg, J. Dunn, W. Watkins, S. A. Watkins.

*New Members.*—The following were approved as members of the under-mentioned Branches:—Morchard—G. Collins, R. Dawson, D. McKenzie ; Woodleigh—F. Tholborne ; Coonalpyn—F. F. Whitehead, E. J. Hopcroft ; Mount Gambier—H. M. Hogan, J. Pick, H. Sutherland ; Waikerie—C. G. Gill, R. Henderson ; Milang—L. T. Stubbs, J. Oakley, Wm. McMillan ; Monarto South—F. A. Bretig ; Mallala—C. T. Moody, H. Catt ; Roberts and Verran—V. C. McCallum ; Koonibba—A. Kloeden ; Kybybolite—D. Pettit ; Penong—A. Shillabier, sen., A. Shillabier, jun. ; Lameroo—G. Hayman ; Port Broughton—R. H. Bowden ; Leighton—W. H. Turner ; Wilkawatt—A. Bates.

## POULTRY NOTES.

By D. F. LAURIE, Poultry Expert and Lecturer.

### DROUGHT AND THE POULTRY INDUSTRY.

The practical failure of crops has resulted disastrously on the poultry flocks of the State. When the spring hatching season arrived the season's prospects were so poor that many breeders decided to curtail their operations very considerably. Later on, when farmers found that they had no wheat for their fowls and that prices were rising rapidly, large numbers of poultry of all sorts, including productive laying hens, were sent into market or were killed and eaten instead of butchers' meat. This sacrifice of our poultry flocks has been going on for some time and will continue. It is true that here and there breeders are holding to the best of their birds in anticipation of the great demand for eggs and birds in the future. As similar conditions have been experienced in the other States, and to some extent in New Zealand, it is more than likely that extreme prices will be the rule in the near future. The experience of the egg market last spring fully realised my often expressed anticipations. It has always been my contention that the opening of overseas markets was imperative in the interests of our producers. It was tacitly admitted during the past glut season that supply had overtaken demand, and breeders had to accept lower prices than had been the case for years. Owing to the war it was impossible to obtain space in any boats with a view of exporting to England. The effect of the war has been to cut off most of the customary supplies of eggs, and in England abnormal prices have been paid for eggs during the year. There are a good many owners of large flocks of poultry, and, as producers of large quantities of eggs, these breeders are much disgusted at the low prices here. When normal conditions return it is evident that there will be no trouble in organising several shipments each year to England. At the present time reliable eggs are scarce, and the published market reports confirm this fact, yet the price of eggs is pence lower than conditions warrant. The practice of cold storing

and pickling eggs may be all right from the point of view of the speculator and manufacturer, but such practices are all wrong from the producer's standpoint. At least a fair proportion of our glut eggs should be sent right away from Australia.

It may be argued that the wholesale slaughter of poultry will mean a continued shortage; that does not necessarily follow. I think the drought has taught, among other things, that every farmer should own a flock of productive poultry. It is gratifying to note that farmers in general are taking much greater interest in poultry, and are adopting more modern methods of housing, feeding &c. On many farms, in the past there have been too many unproductive birds, and if the majority of these have been got rid of there is a chance that the farmers will stock up again with modern utility breeds. Our harvests will soon again bring prosperity and ample food for thousands of productive fowls, and our markets are sure if only we forward produce of the highest quality. For years after the war there will be an enormous shortage of eggs in Europe, and the prices ruling will offer Australia a splendid market. The outlook for the poultry industry in Australia is most encouraging, and it behoves all interested to make the best of the opportunity.

#### GREENFEED FOR POULTRY.

A lesson the drought has taught is the necessity for ample provision of water. On the average farm the lack of proper water supplies has always been a drawback. There has been little systematic effort in sinking wells and making dams and tanks. There are exceptions, but these only accentuate the fact. There are, of course, localities where the question is most difficult, but there are numerous localities where proper water supplies would be the greatest boon. Green food should form from 40 to 50 per cent. of the total food consumed by poultry. A comparatively small supply of water on a farm would ensure the growth of more than enough green foods, and under such conditions egg production would be more profitable. Kails, rape, barley, rye, silver beet, and last, but most important of all, lucerne, are suitable for poultry, and large crops can be grown on small areas of rich soil, if properly attended to. It is well known that farmyard manure is wasted on many farms, and yet for lucerne and the other fodders mentioned it is invaluable. I am not writing an article on growing fodders, I am emphasizing the need and economy of growing such fodders for poultry. I may, however, say that anyone who adopts this advice will do well to pay particular attention to the preparation of the soil before sowing or planting. Cultivate well, manure

liberally, cultivate again, and then grade. A small area thus treated gives far better growth and for much less labor than does a large block ill-prepared.

#### MARKETING EGGS.

Why is there so much waste in the egg branch of the industry? On all hands we hear of crop failures and lack of cash. Yet some of those who keep poultry and market eggs must be very careless. The market reports continually state that eggs arriving in Adelaide are of poor quality, stale, and many decayed. This loss is easily preventible, and its continuance is a reflection on those concerned. This is not the time to waste valuable produce. The infertile egg does not go bad.

D. F. LAURIE, Poultry Expert and Lecturer.

## EGG-LAYING COMPETITION.

The Minister of Agriculture (Hon. T. Pascoe, M.L.C.) has, in view of the extreme prices ruling for wheat and other poultry foods, instructed the Director of Agriculture to cancel the arrangements for the egg-laying competition it was proposed to start on April 1st. The Minister is of opinion that the necessity for economy renders it imperative that all work not essential to the purpose of the poultry station shall be curtailed.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

### CONFERENCE OF MID-NORTHERN BRANCHES.

The annual conference of Mid-Northern Branches of the Agricultural Bureau was held at Crystal Brook on Friday, February 26th. The Department of Agriculture was represented by the Director of Agriculture (Professor Perkins), the Poultry Expert (Mr. D. F. Laurie), the Wool Instructor (Mr. Henshaw Jackson), Messrs. F. Coleman (Vice-Chairman), G. Jeffrey and J. Miller (Advisory Board), G. G. Nicholls (Secretary), and H. J. Finnis. The following gentlemen attended as representatives from the undermentioned Branches:—Crystal Brook—M. Weston, H. H. Nicholls, James B. Greig, J. Pridham, J. Teakle, R. L. Davidson, William Jasper, William Hutchinson, W. W. Robinson, R. Parry, H. Billinghamurst, James Forgan, W. J. Venning; Booleroo Centre—N. L. Brooks, R. W. Stanton; Beetaloo Valley—A. Gawler, P. Curtin, J. Ryan; Narridy—J. E. Nicholls, Tom R. Melbourne; Redhill—E. Steele, J. J. Kelly, W. Pengilly; Gladstone—S. Masters, R. H. Coe, John Eley; Wirrabara—P. J. Curnow; Georgetown—M. J. McAuley, George E. Hill; Canowie Belt—G. A. Noll, H. A. Wedding; Yongala Vale—C. Fowler; Port Pirie—F. A. John, A. M. Lawrie; Laura—E. G. Blesing, J. S. Giles; Whyte-Yarcowie—S. F. W. Robinson, George F. Jenkins.

### THE CHAIRMAN.

The chair was occupied by Mr. R. R. Shaw, who, in asking the Vice-Chairman of the Advisory Board of Agriculture (Mr. F. Coleman) to declare the conference open, expressed regret that the Minister of Agriculture (Hon. T. Pascoe) had found it impossible, owing to a call to the South-East, to attend the fixture, extended a hearty welcome to all the visitors, and trusted that they would gain much valuable information from the deliberations, and be stimulated in the pursuits in which they were engaged.

### OPENING ADDRESS.

The Vice-Chairman of the Advisory Board (Mr. F. Coleman) briefly referred to the great interest which the Minister of Agriculture had always manifested in the aims and achievements of the Agricultural Bureau, and his strong desire to promote the welfare of the farming and allied industries; paid a tribute to the useful work accomplished by the Chairman of the Advisory Board (Mr. G. R.

Laffer), mentioned that besides himself the board was represented that day by the Director of Agriculture (Professor Perkins), whose splendid experimental and investigational work at Roseworthy College had not been equalled in any other State in the Commonwealth, Messrs. G. Jeffrey and J. Miller, the Secretary (Mr. G. G. Nicholls), and the Assistant Secretary (Mr. H. J. Finnis). Since the conference at Gladstone, last year, the Northern District of the Bureau had been divided, so that there were now a Northern and a Lower Northern District. By the adoption of that policy it was considered that the efficiency of the numerous branches comprehended within the boundaries of the two divisions would be increased, and that the members individually would derive greater benefit from the annual gatherings than hitherto had been possible. It pleased him immensely to note the hopefulness which characterised the spirits of the primary producers, who evidently were determined to make the best of the unhappy circumstances in which, through the drought, they found themselves placed.

#### EXPERIMENTAL WORK.

As one who was interested in experimental work, it was particularly gratifying to him to notice that the Director had selected a site for an experimental farm on Eyre's Peninsula, which was to form a centre from which plots on private farms throughout the district would be worked. This system, he thought, had everything to commend it.

He expressed the hope that the conference would prove instructive to all, and assist further to hearten up the farmers throughout the Northern Areas.

#### THE MEAT EXPORT TRADE.

In a paper dealing with this subject, Mr. George F. Jenkins (Whyte-Yarcowie Branch) said:—"The importance to the primary producer individually and collectively makes a paper on this subject eminently suitable for a conference of farmers. Hence my attempt to throw a little light on the subject, and to offer a suggestion or two for fostering the industry. We are all well aware that during the last few years there has been a steady upward tendency in the price of all fat stock, and the prices are much more regular all the year round than formerly, when we were accustomed to have to take ruinously low prices for our stock in times of plenty. Briefly, the fact is that the demand for meat has overtaken the supply, and with the export facilities now at our disposal, a glut in the local market is almost an impossibility. The demand for meat, with its

consequent enhanced prices, is world-wide, and this is a fact that we should be fully prepared to take advantage of. North America, formerly the greatest beef-exporting country in the world, is now scarcely able to feed her own population, owing to the fact that while her population has enormously increased, much of the country formerly used for ranching is now devoted to agriculture, wheat-growing having proved more profitable than cattle-raising.

"Against this we have to consider the fact that importations of frozen and chilled meat into the United Kingdom have enormously increased, as the following figures will show:—In the year 1894 there was imported into the United Kingdom from all countries 1,239,469 quarters of frozen and chilled beef. In 1913, only 19 years later, importations had risen to 5,608,834 quarters—a truly wonderful increase in so short a time. Of this total Australia contributed 1,084,832 quarters, while Argentine accounted for 4,021,531 quarters. Now let us look at the frozen mutton and lamb business.

"Here the same enormous expansion of importations into the United Kingdom is manifest. In 1894 the United Kingdom imported 4,324,109 carcasses of mutton and lamb, a business which had increased by 1913 to 12,937,165 carcasses, Australia's share showing the very respectable total of 4,442,517. In this connection, however, we must note that during the last four or five years our exports have remained practically stationary.

"Now, with this enormous increase in trade has come also a big increase in prices. Australian frozen beef (hindquarter) was worth 2½d. per lb. in Smithfield Market in 1896, and 4d. in 1913; while on January 16 of the present year the quotation was 6½d. per lb. Similarly we notice that Australian lamb was worth 3½d. per lb. in 1897, and 5½d. in 1913, January's (of this year) quotation being 6½d. per lb. These figures should bring forcibly to our minds the importance of expanding our export meat trade to the greatest possible extent. That being so, we may well consider how we can individually help, and hence benefit, in this direction.

"In my opinion it is to be regretted that so many of our farmers, particularly within the rainfall area, do not go in more for stock-raising in connection with their farming operations. Travellers have often noted the exceedingly small number of stock kept on most of our South Australian farms.

"Surely it will pay us to handfeed our stock for a portion of the year, and thus carry many more than we do at present. In South Australia, which must be regarded as a comparatively dry country, we systematically harvest our crops and burn our straw and wheaten chaff, each of which might be made to keep a certain number of

stock each year with the addition of a little bran or other nourishing food. Contrast our system with New Zealand or most of the richer countries, where we find that the straw is saved, and used as a supplementary fodder, thus enabling many more stock to be kept on the farms, and such turned to profitable account.

"It is time we called a halt to this policy of extravagance which has characterised our method of harvesting during the past few years. The complete harvester must be regarded as the greatest sinner in this respect. With the prices now obtainable for fat stock, and the certainty of good prices in the future, it will, I feel sure, pay to cut and thresh at least a portion of our crop each year, turning into meat and profit that which we now burn. We have regarded it as too much trouble to save our cocky chaff in recent years, although at present this much-despised fodder has achieved quite a remarkable popularity.

"I am met with the argument that it will not pay to adopt this method of harvesting, as labor is too scarce and dear. Well, I feel sure that if the experiment were but tried and properly carried out the binder and thresher would become much more popular in South Australia. I think that the small farmer has most to gain from this practice of mixed farming and utilising waste products. If the labor problem becomes too acute a little co-operation amongst neighbors would get over the trouble to a great extent, and the small farmer would have more than one source of income. Let us then utilise our farms and products to the greatest possible extent. Remember that the more stock we carry the more do we enrich our land, and the greater will be our source of income. The present world-wide demand for meat is Australia's opportunity; it is no illusionary shadow. Let us grasp the opportunity that offers, and make the most of it, thus helping forward not only our individual ends, but the prosperity of the State as a whole."

#### DISCUSSION.

Mr. W. J. Venning (Crystal Brook) congratulated the writer on the paper. Some people, he said, objected to hand-feeding sheep, but this was an agricultural practice that would become very popular. If they were going to rear good lambs, it would be necessary for them to choose good ewes, and feed them well. If any industry in South Australia was in need of development, it was that of raising cattle and sheep for market. Mr. George Jeffrey (Advisory Board) said the paper dealt with a subject of vital importance to South Australia. He mentioned the experiments which had some years ago been conducted at the Roseworthy Agricultural

College, under the superintendence of Professor Perkins, in determining what could be done by the ordinary farmer in the way of growing sheep. In his opinion the meat export trade from this State was still in its initial stages, in comparison with what could be done. Professor Perkins also congratulated the writer on producing an interesting paper. Mr. Jenkins was advocating a practice which was bound to come sooner or later. With reference to the utilisation of chaff and straw, he had had some experience of the binder and thresher, and he could say definitely that they would find it no more expensive to cut the crop with the binder, and thresh it, provided there was some value to be put on the straw, than to harvest in any other way. If the straw was worth only 10s. per ton it would amply repay them to reap in that fashion. At Roseworthy Agricultural College they had always disposed of the straw at 35s. per ton in the stack. Of course, at that price there was only a limited demand. The difficulty was not one of expense, but of getting the labor. If they were threshing straight out from the fields, and the fields were not too close, they would want at least two wagons, and possibly a small dray, two pitchers, and one loader. To run the machine a feeder, bagger, bandcutter, unloader, and two men in charge of the straw would be necessary. Consequently the total number of men required would be from 10 to 12 at the very least. This was a big drain on the available labor. However, if they could get the labor, it was one of the best practices they could adopt.

#### FARMERS' CLIPS.

The Wool Instructor (Mr. Henshaw Jackson) delivered an address on the preparation of farmers' clips for market, and on other matters. He had made a practice, he said, of meeting the farmers in the shearing sheds, to teach them how to handle and class their clips, and he hoped that when the drought was over steps would be taken to enable him to meet bodies of them at least once a week while the shearing was in progress. After having discussed at length the special requirements of the worsted and woollen sections of the trade, he indicated the lines along which classing should be done. He strongly advised farmers to remove the burry wool from the fleeces which were only slightly touched. The burry side skirtings could be made up in one line, and would realise fair prices, and the remainder of the fleece would bring its full value, whereas if the burry portions were left on the fleece the value of this would be materially reduced. They should test their wool for soundness of staple before they put it in the top lines, and, of course, they must not mix the different qualities. There was not the slightest reason

why the small clips got up well should not meet with as keen competition as did the larger ones. It was important to remove the stained portions of the wool, or lower price would result. The classing of clips resolved itself simply into matching the various fleeces, and no farmer need have any difficulty with that. He had frequently noticed faulty methods of branding the bales, and therefore advised farmers to use properly cut stencils. He concluded an instructive address by advocating a more widespread use of lucerne on small areas. There were many places where producers could successfully irrigate from three to four acres, and in the aggregate quite a large area could be handled in that way. He had experimented with various systems of overhead watering, and had come to the conclusion that the best was one which had an extensive vogue in the United States. It was economical and cheap, and practical men who had seen it had immediately resolved to instal it on their properties.

#### WATER CONSERVATION AND BORES.

Mr. J. Miller (Advisory Board) strongly advocated the erection of a weir at the junction of the Broughton and Rocky Rivers. The water which could thus be dammed back after each flood, he said, would supply sufficient to meet the requirements of the hundreds of Pirie and Wandearah for three or four years. He remembered when in that district he had been obliged to travel through 20 miles of water. Mr. Miller then described his lucerne-growing operations at Morphettville, and mentioned that as a result of having struck a splendid supply of good water—in fact, it overflowed the top of the bore—he had been able to produce an enormous quantity of fodder. What he and a few others had accomplished in that respect could be done by others in many places. A report he had received from the Government Geologist stated that there were 250 wells and bores in the immediate neighborhood of Adelaide; no account had been taken of the large number of small bores in such suburbs as Rose Park and Unley, where small supplies had been obtained. The principal water-bearing area in the vicinity of Adelaide was that which lay between the city and the coast. Good water had been obtained from Brighton to Adelaide, and probably would be found beneath the shallow brackish water used for lucerne-growing in some of the western suburbs. There were several districts in which only brackish water had been obtained, but which were well worth prospecting for deep water. Four bores were supplying to the Adelaide mains more than 1,000,000 galls. a day of good-quality water. These were at Hilton, Marlestone, Plympton, and Morphettville.

Mr. Miller was responsible for the sinking of a bore at the Blind, Deaf, and Dumb Institution, at Brighton, some nine months ago. To show what a wonderful success it had been he quoted the following letter from the superintendent (Mr. Samuel Johnson):—"The engine raises 10,000galls. an hour, and there has so far been no sign of any decrease in the volume of water. It costs 1½d. per thousand gallons, but this does not include the cost of repairs to the engine. We have watered from the bore during the summer months 1 acre of vegetables, 2 acres of lucerne, 3 acres of maize, and a large number of orange and other fruit trees. The vegetables are superior in size and quality to any raised in former years. Pumpkins weigh up to 80lbs., watermelons to 30lbs., and the tomato, cucumber, and trombone crops are the largest and the finest I have ever seen. We have so far made five cuts of lucerne, and the maize is standing from 7ft. to 8ft. high. A large quantity of summer vegetables may be seen here stored for winter use. This is out of all proportion to the quantities stored in former years. I estimate the value of the crops grown this summer at from £250 to £300. It must be borne in mind that we have 15 cows, and have purchased only 5 tons of hay and 5 tons of chaff for them. At present we have an abundant supply of milk and butter for the whole household—120 persons. The total cost of bore, engine, pumping plant, and fluming was about £400. It can be readily seen that profit from the gardens will very soon pay the whole of the cost. I am preparing for an extension of the lucerne paddock and for various improvements in the fruit and vegetable garden. We possess a large number of poultry and nine pigs, and no food whatever is bought for these at present, as they are fed with vegetables and scraps from the tables. The pigs are in particularly fine condition, and we get more eggs than we ever had before at this season of the year."

#### INVESTIGATIONS IN THE NORTH.

Mr. Miller said he believed boring might be carried out successfully in various places in the Northern Areas. Many years ago at Merriton he put down two bores and struck brackish water at 70ft. With his added experience he was confident that had they continued the operations they would have struck useful supplies.

Mr. W. J. Venning considered that if bores were sunk from 300ft. to 1,000ft. in the Crystal Brook district good supplies of water would be obtained. The Government should be asked to investigate the subject.

**Afternoon Session.****COMMERCIAL FRUITGROWING.**

Mr. P. J. Curnow (Wirrabara) contributed the following paper under this heading:—'During the last 10 years fruitgrowing on a commercial scale has made considerable headway in this State. The possibilities which the apple export trade held out for a substantial and remunerative return within a reasonable time from the planting of an orchard encouraged many to embark in that enterprise. The continuance of good seasons, too, over a lengthened period gave confidence to planters, and much land that was really unsuited to the purpose was planted, but has now, when dry and long summers come, proved its unsuitability.

In planting fruit trees on a commercial scale two principal factors have to receive very careful consideration. The first is the question of locality, and the second that of soil suitability.

Dealing with the first, it may be pointed out that many failures can be traced to the fact that certain varieties of trees are growing out of their element. If apples, cherries, pears, and plums require a deep soil, with a good subsoil, then it is a mistake to plant such trees in shallow alluvial in a hot or warm district, for while they do well in normal years, when a long, dry summer sets in, such trees suffer stress, and soon become unprofitable. On the other hand, peaches, apricots, and nectarines would fail on heavy land when only a few years old, but would thrive on lighter soil under ordinary conditions.

While admitting that every landholder should attempt to plant at least some fruit trees around his home, providing there is a reasonable chance of their growing, thus adding to his home comfort and the value of his property, yet fruit growing on a commercial basis requires more careful consideration of the exact needs of each variety of tree, which involves skill and experience on the part of the planter; therefore there is an obvious difference between planting for the purpose of making a living out of fruit growing and planting for home requirements.

When we come to analyse the question of suitability of locality for commercial growing, we find that this State, especially in the North, possesses a limited number of districts in which fruit can be profitably produced. In Wirrabara, Beetaloo, Clare, and, lower down, Angaston, Barossa, Nuriootpa, and one or two others, we find most fruits do well; whereas, even in the same districts, only on the more open country, poor success attends the growers' efforts, as

away from the protection afforded by ranges of hills, hot winds and a lesser rainfall tell against success. When we see everywhere around us the poor success obtained by farmers and others who have attempted fruit growing, even on a small scale, then are we forced to admit that to succeed on a large scale ideal conditions must be found. In Wirrabara Forest, even with its heavy rainfall, good land is difficult to obtain, and much that has been planted is proving quite unsuitable to the varieties of trees planted upon it, and must finally prove unprofitable.

Having considered the points raised in the foregoing remarks, the prospective grower should consider the purpose for which he proposes to plant. If he desires to enter into the apple export trade, then land suited to the production of apples must be found. In the writer's opinion, a good grey or dark loam, with a red clay subsoil a foot or so under the surface, is an ideal soil. Yellow or white clay is generally of a hungry character, and does not give such good results as the first-mentioned. The orchard site should, here in the North, face east or south, and if possible should be on a gentle slope. The planting of land facing north or west is a mistake, as the great heat from a merciless summer sun soon dries out soil, and is more liable to sun-scald fruit. The planting, too, of steep hillsides here in the North is a serious mistake, as the trees suffer more than on more level ground, owing to an excess of drainage. In the Adelaide Hills, with a more regular rainfall, success is more likely, and trees can be grown profitably on such country. To succeed as an apple exporter it is necessary to enter into the business on a large scale. At least 2,000 trees of good export reputation should be planted. While 1,000 will give a good return in a heavy season, in the off year a very limited quantity will be obtained, and probably a loss on the year's operations will result. By planting the larger number a large crop one year should help to tide over a light crop in other seasons. When we come to consider the varieties that are to be planted, little difficulty confronts the skilled grower. After so many years of experience in the handling of export fruit, he knows that about four of five names exhaust the list. In the writer's opinion the Cleopatra, Jonathan, Sturmer Pippin, Dunn's Favorite, and London Pippin head the list, and in laying out a large orchard the two first-named should constitute about two-thirds of the whole block, as they are regular bearers, and have won an excellent reputation in the Old World fruit markets. The question of soil preparation is generally well understood by the average grower, and therefore there is no need to elaborate upon it

here. Before leaving the subject of planting, however, it may be necessary to emphasize one other point. Reference is now made to the need of planting the varieties so that cross-pollination will result. If a block, say, of Cleopatras only be planted, poor crops will result, as although the trees will flower well, fruit will set poorly. If, on the other hand, rows of Cleopatras be alternated with rows of Jonathans, excellent crops should set. The writer favors the planting of two rows of a variety, then two rows of another sort, and again two rows of the first sort, all through the orchard. By adopting this method each tree is exposed to the cross-fertilising influence of another in the next row, and by planting in two rows of a sort, spraying can be carried out each side by the sprayer at one time.

The foregoing remarks in reference to soil and locality apply to all other fruits. Ideal conditions must be found to suit each variety if the business of fruit production is to be carried on as a business; the neglect to so select the land, and to plant it according to the variety most suited to it, will lead to an unprofitable venture. As a rule a landholder, upon deciding upon entering into the production of fruit, plants the land he has at hand, irrespective of its suitability or not, and hence we see many poor orchards and unprofitable ones. It may be that a would-be grower decides upon entering into the production of apricots and peaches, for instance, for the Broken Hill and Port Pirie trade. The skilled grower knows that alluvial river flats or rubble limestone hills are most suited, and selects accordingly, providing his locality is a suitable one. For early peaches he plants Brigg's Red May, High's Early Canada, and probably Alexander's Early, and a few others on his highest suitable land, and selects a spot facing north, to catch the early sun, thus producing the very earliest fruit. The same varieties on low-lying land ripen a week later. For second and mid-season varieties he has a long list from which to select. When planting his late sorts he selects a southern aspect, if he can find the right soil, thus retarding the ripening of his later fruits by some days. The absence of practical knowledge of his subject often leads the would-be planter into difficulties that are costly and that take years to rectify, whereas a few hints at the outset may be of value. In conclusion, the need to study carefully the whole question of commercial as distinct from the home or amateur production of fruit in all its branches cannot be too strongly emphasized. If a prospective planter can secure first-hand information by seeking employment with a skilled man for one or two seasons, he can gain knowledge that should be invaluable in his after work."

Mr. H. Billinghamurst, B.A. (Crystal Brook) congratulated the writer of the paper. He was pleased to notice that Mr. Curnow drew a distinct line of demarcation between growing fruit for home use and for commercial purposes. Every landholder, he thought, should have a few trees on his property. The suggestion made by Mr. Curnow that the trees should be planted in double rows was a good one. There was always the difficulty with the big blocks of trees in connection with the pollenisation, and if the varieties were spread about too much, additional labor was involved in spraying.

Mr. Coleman (Advisory Board) agreed. He mentioned that the subject of cross-fertilisation had received a great deal of consideration on the part of pear growers at Renmark.

*(To be continued.)*

#### AGRICULTURAL BUREAU CONFERENCES.

The Conference of Lower Northern Branches of the Agricultural Bureau will be held at Riverton on Thursday, March 11th. The South-Eastern Branches will hold their Conference at Mount Gambier on March 24th. The fixture will be attended by the Minister of Agriculture (Hon. T. Pascoe, M.L.C.), the Director of Agriculture (Professor A. J. Perkins), the Dairy Expert (Mr. P. H. Suter), and the Wool Instructor (Mr. Henshaw Jackson).

The prices quoted in South Australia are for farmers' lots on trucks, Ports Adelaide, Pirie, and Wallaroo; and those in Victoria for parcels on trucks, Williamstown and Melbourne. The prices officially fixed in New South Wales and Western Australia, viz., 5s. and 7s. 4d. per bushel respectively, remained unchanged.

## DAIRY AND FARM PRODUCE MARKETS.

A. W. Sandford & Co., Limited, report on March 1st—

**BUTTER.**—During February some high temperatures were recorded, and this had its effect on the quality of consignments sent forward. Demand and turnover, however, were good. “Alfa” is selling at 1s. 4½d. per lb.; “Primus,” 1s. 3½d.; choice separators and dairies, 1s. to 1s. 2d.; well-conditioned store and collectors’, 9½d. to 10½d.; heated lots lower.

**EGGS.**—Prices further firmed early in the month, but this seemed to have the effect of turning the attention of some of the consumers to pickles, so that a set-back in values then occurred, and closing sales were several pence under the highest point obtained. Present quotations are, fresh hen eggs, 1s. 1d. per dozen; duck, 1s. 2d.

**CHEESE** continues to experience active inquiry, and prices are well maintained. Rates now ruling are from 7d. to 7½d. per lb. for large to loaf.

**BACON.**—The turnover continues substantial, in spite of the firm values that are ruling. Best factory-cured sides are selling at 10d. to 11d. per lb.; hams, 11d. to 1s. per lb.

**HONEY** is in very good request, both for local and export markets, the production, as forecasted in our last report, being less than last season. Present rates are—Prime clear extracted honey, 3½d. per lb; beeswax, 1s. 3d. per lb.

**ALMONDS.**—Prices ruled a little better than during January, and demand quickly absorbed all parcels coming forward. Brandis are selling at 8d.; mixed softshells 7d.; hardshells 3½d.; kernels, 1s. 2½d. to 1s. 3d. per lb.

**LIVE POULTRY.**—Extensive pennings were again recorded throughout February, and demand was keen for anything approaching quality, but many lots that reached the market were not fit for table purposes. Heavy weight table roosters brought 3s. to 4s. each; nice-conditioned cockerels, 2s. 6d. to 3s.; small and medium, 1s. to 2s.; plump hens, 1s. 6d. to 2s.; small and light, 1s. to 1s. 3d.; ducks, 2s. 3d. to 3s. 3d.; geese, 2s. 9d. to 3s. 6d.; pigeons ranged from 3d. to 6d.; turkeys, from 6d. to 10½d. per lb. live weight for fair to good table birds.

**POTATOES AND ONIONS.**—The early potato crop in the Mount Gambier district has already nearly cut out, and considerable quantities are therefore being imported from Victoria and Tasmania. Prices have slightly improved. Onions—Much better supplies are now available, and consequently rates are decidedly lower. Quotations—Potatoes, £5 15s. to £6 5s. per ton of 2,240lbs. on trucks Mile End or Port Adelaide. Onions, £8 per ton of 2,240lbs. on trucks Mile End or Port Adelaide.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of February, 1915, also the average precipitation to the end of February, and the average annual rainfall.

| Station.                   | For Feb., 1915. | To end Feb., 1915. | Average to end Feb. | Average Annual Rainfall | Station.               | For Feb., 1915. | To end Feb., 1915. | Average to end Feb. | Average Annual Rainfall |

\* No report received during the month of February. † Formal report only received.  
 ‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

April 14th, and May 12th, 1915.

## EDITORIAL.

[It is regretted that, owing to the continued shortage of paper, it has been found necessary to considerably reduce the space allotted to reports of meetings. For this reason many very good papers, which under ordinary circumstances would have been printed *in extenso*, have had to be dismissed with passing mention. This applies more particularly in cases where the subjects have been lately dealt with extensively by other Branches and reported fully in the *Journal*.—Ed.]

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

## REPORTS OF BUREAU MEETINGS.

Edited by H. J. FINNIS

## UPPER-NORTH DISTRICT.

(PETERSBURG AND NORTHWARD.)

MORCHARD (Average annual rainfall, 11in. to 12in.).

January 30th.—Present: 10 members and one visitor.

CARE OF MACHINERY.—A short paper was read by Mr. W. Twigden. He advised farmers on small holdings not to purchase large machines, as this would necessitate keeping big teams, which should be avoided except where absolutely necessary. When not in actual use all implements and machinery should be kept under cover, and their woodwork painted, &c., and be generally overhauled. He instanced a case where one man had got eight years' service from a binder through exercising care with it, whilst another's implement was worn out at the expiration of three years simply because no care had been taken of it. The condition of the land on which the machinery was used had a great bearing on its length of life. Where hay was to be cut he would first roll the land to reduce the wear and tear of the binder or mower. Discussing the paper, Messrs. E. J. Kitto and H. G. Kupke (Hon. Secretary) indorsed the writer's remarks.

BINDER AND THRESHER.—Mr. R. Kitto read a paper. A crop to be threshed, he said, was ready for the binder 10 to 15 days earlier than if to be taken off by the stripper, consequently the straw would then have more nutriment in it. All weeds, &c., would then be taken off in their green stage. Wheat taken off in this manner and allowed to mature in the stack was a better sample than that which matured in the field, and also made better flour. Another advantage was that it was not so likely to be damaged by storms. After the hay had been stacked it could be threshed at the most convenient time to the farmer,

probably between harvest and next seeding. With the old machine, that was the bare thresher without the shaker and winnower, it was possible to thresh from 15 to 20 tons per day and stack the straw. An advantage of the thresher over the header was that it knocked out the whole of the grain, and consequently the straw stack was not so damaged by mice. When stacking the straw it was advisable to sprinkle a little salt over each layer. A discussion followed. Mr. E. J. Kitto considered that the binder and thresher should be used more extensively in this district. A stack of straw would then always be available. The Chairman (Mr. J. W. Reichstein) and Hon. Secretary (Mr. H. G. Kupke) also held this view.

**TARCOWIE.**—Mr. W. L. Ferris read a paper in which he put forth several suggestions for the better working of the Agricultural Bureau. Among other things, he emphasized the necessity of regular attendance by members, and punctuality. A discussion followed.

### MIDDLE-NORTH DISTRICT.

(PETERSBURG TO FARRELL'S FLAT.)

**BURRA** (Average annual rainfall, 17.82in.).

November 28th.—Present: 11 members.

**THE WATER SUPPLY ON THE FARM.**—Mr. H. H. Thomas read a paper. For convenient working, he said, it was necessary to have a permanent water supply on every farm. A dam should be constructed conveniently near the homestead, and care should be taken to keep the water as clean and pure as possible. Stock walking round the dam consolidated the earth near it, and this afforded a very good water catchment; but manure and other foul matter lying about was liable to find its way into the water and form a breeding ground for germ life. To prevent this the dam should have a bank all round. However large the dams might be, he said, farmers generally could not be sure of a permanent supply, so it was necessary to obtain water by boring. He considered the divining rod a great help to farmers in determining where to sink their bores. Boring was cheaper and quicker than well sinking, and was not associated with any danger. He recommended pushing down a casing where there was any likelihood of drift, and would put down a 2in. delivery and suction pipe and a 3½in. cylinder long-stroke brass pump well down into the water, as it was much easier to force the water than to pump it. For ordinary purposes a 10ft. mill with a 3,000gall. storage tank would be sufficient, but if stock were to be watered, an engine, say 2 h.p., would be necessary to ensure water always being available. The self-action gears of the mill for keeping the tank full, the ball and float valve on the trough to regulate the filling of same, and the screw greasers of the mill were all very convenient. He favored sprinklers for irrigating lucerne, and spoke of an improved pattern, which was capable of watering a plot 180ft. across without being moved. Members discussed the paper at some length, and were all in favor of bores. Sprinklers were preferred to flooding for irrigating lucerne.

**CRYSTAL BROOK** (Average annual rainfall, 15.62in.).

December 5th.—Present: 29 members.

**CO-OPERATION.**—The two papers on this subject which were written for the Annual Congress were read. An animated discussion followed, the majority of members being in favor of co-operation among farmers. The Hon. Secretary (Mr. W. W. Robinson) presented a report on the experimental plots (variety tests) which had been carried out under the supervision of the above Branch. In consequence of the excessively dry season the results were not very satisfactory from an experimental standpoint. It was decided to carry out the tests again next year.

**MOUNT BRYAN EAST** (Average annual rainfall, 16in.).

October 31st.—Present: seven members and three visitors.

**DROUGHT.**—A paper was read by Mr. F. Thomas. The severity of the present drought, he said, emphasized the necessity for preparing against such periods in future. It had strongly impressed on farmers the need for conserving straw, cocky chaff, &c., for horse feed. Had this fodder been conserved during previous good seasons, much stock which had died, or had been sold at very low prices this year would have been kept on the farms. The value of a permanent water supply had also been made evident. He advised farmers to sink wells or make provision to catch sufficient rain water to tide over a period of shortage. Droughts, he said, also had a few beneficial effects. Pests, such as rabbits, grasshoppers, &c., were greatly reduced. Old stock was disposed of, and there was a general culling out of all inferior stock on the farm, only the best being kept. A discussion followed the reading of the paper.

**PORT BROUGHTON** (Annual average rainfall, 14.44in.).

February 7th.—Present: seven members and one visitor.

A discussion on the value of straw as a fodder was initiated by Mr. G. E. Pittingale. An instance had come under his notice, he said, of a farmer who had fed his horses with chaffed baled straw. Some of the animals died on this diet, and then he changed the diet to hay chaff, and the other horses that were ill recovered. Pressed straw was more injurious to horses on account of it being broken into small pieces. Mr. Routly stated that his horses had done well on a mixture of hay and straw chaff. They had also been fed on chaffed straw alone with no ill effects. Mr. W. B. Whittaker mentioned that his animals had lived on chaffed straw only for some time. They had done better on old wheaten straw than on good oaten straw. A visitor mentioned that if horses had to be placed on a chaffed straw diet, a small quantity of pollard would prevent scouring.

**SPALDING** (Average annual rainfall, 20.25in.).

October 3rd.—Present: nine members and one visitor.

**HAY.**—Mr. T. Walsh read a paper. The following varieties, he said, were good hay wheats:—King's Early (which would grow well on all classes of soil), Marshall's No. 3, White Tuscan, Yandilla King, and Gluyas (cut on the green side). He preferred to stook close up to the binder as the sheaves were then better for stacking and of better color. Long stooks of four sheaves wide were best able to withstand rough weather. He contended that oaten hay should be grown more extensively in this district. This should be cut when the straw was a purple or pinkish color, with a golden tinge at the heads. When stackbuilding, a foundation of straw or wood should be put down. If the stack was to stand for a number of years it should be built butts outwards, but otherwise he preferred to place the sheaves heads outwards. The walls should slope outwards as the stack rose at a grade of 4ft. in 20, the centre of stack being kept well up. He preferred square-cornered stacks. Each layer of hay should be sprinkled with a few gallons of water, and also with salt. If the hay were very dry the addition of molasses would be found advantageous. It was only a matter of a few years when every farmer would have a hay shed. Members discussed the subject. Some favored iron roofing for stacks, whilst others preferred thatching.

**NORTH BOOBOROWIE, November 3rd.—FORAGE CROPS.**—A paper under this heading was read by Mr. A. V. Simpson. The advantage of forage crops in conjunction with the practice of cropping every third year, he said, was that they enabled the farmer to breed a few sheep. The droppings from these sheep greatly enriched the land, to the advantage of the following wheat crop. After any March rains, portion of the stubble could be sown with rape, barley, mustard, or perhaps peas. In some districts fodder crops were grown in the winter, and these, together with the stubble after harvest, and the natural herbage available, provided feed for sheep during the whole year. The crops should be sown on different land each year, so that the whole of the farm would be benefited by the sheep droppings.

### LOWER-NORTH DISTRICT. (ADELAIDE TO FARRELL'S FLAT.)

CLARK, October 2nd.—MARKETING PRODUCE.—Mr. R. Hunter dealt with this subject in a lengthy and interesting paper. He mentioned the necessity for producers keeping well in touch with the markets, and urged the wisdom of marketing everything in as attractive manner as possible. Members were much interested in the subject.

### YORKE PENINSULA DISTRICT. (TO BUTE.)

MOONTA, October 30th.—GRUBS IN WHEAT CROP.—Mr. W. B. Stacey stated that he had noticed a grub, about  $\frac{1}{2}$  in. long, light grey in color, with a dark blue head, which possessed hard jaws. It was generally found in light land. He had prevented the spreading of the pest by putting sheep in the fields to trample the ground and make it firm. Mr. E. Nankivell informed members that much of the withering in the crops of this district was not "take all," but was caused through lack of moisture. Some members had known white ants to harm the crops by eating the roots of the plants.

### WESTERN DISTRICT.

#### KOONIBBA.

December 29th.—Present: 11 members and six visitors.

FALLOWING.—In a paper on this subject, Mr. J. Foggo said scrub country could most profitably be worked when fallowing was practised. The objects attained by fallowing were the conservation of moisture, the destruction of weeds, &c., and the production of a good seed bed. The fallowing should be commenced as soon after seeding as possible, and whilst the land was wet. The harrows should follow the plough immediately, and after every rain they should be put over the land. This consolidated the sub-surface, and kept the surface soil in a loose condition. In the event of the growth of weeds becoming too strong to be killed with the harrows, sheep could be grazed on the fallow. In the absence of these, the share cultivator should be used, in preference to the disc cultivator or plough. On no account should this working be to any depth. An interesting discussion followed, in which Messrs. Girsch, Linke, G. Schultz, Schmidt, R. Schultz, and E. Lutz took part. The lack of horse strength and the absence of feed, some members thought, would prevent the general practice of early fallowing.

WHEAT FOR SEED.—Mr. G. E. F. Schultz also read a paper. He referred to the necessity for conducting variety tests of wheats in this district. Three of the most suitable kinds for this locality, he said, were Gluyas, King's Early, and Carmichael's Eclipse. Early wheats would be found most suitable as a general rule on the West Coast. Of the late varieties, Comeback and Yandilla King were good sorts. Grain sown for the purpose of providing seed wheat should be sown on new land or on fallow. It should be allowed to ripen well before being reaped, and particular care should be taken in cleaning all harvesting machinery, &c. Several members agreed that Federation was an unsuitable wheat for this district. Mr. M. Linke had found Carmichael's Eclipse very satisfactory. Mr. A. Schmidt said Federation, Newman's, and Walker's Wonder had been most successful on the Mission Farm this year.

#### ROBERTS AND VERRAN.

January 26th.—Present: eight members and two visitors.

BULK HANDLING OF WHEAT.—Mr. L. Cowley read a short paper. He thought this system of handling grain would not be advantageous to the State as a whole, or profitable to the farmers. On account of the number of small ports from which grain was now

shipped, a large number of elevators would have to be erected, involving a great expense. Under the present system of bagging the wheat the farmer did not lose much on the bags, as these were weighed with and paid for as wheat, and the price that they would realise when sold as second-hand bags was also reckoned in the price paid for bagged grain; and even with bulk handling bags would be utilised to cart the wheat to ports of shipment. Although he did not think bulk handling practicable at present, perhaps in time to come when much larger areas were under crop and a greater acre yield was obtained, and the export shipping was confined to a few of our biggest ports conveniently in touch with the wheat-producing areas, it would be to the advancement of the State to adopt such a system. A discussion followed. Messrs. W. Kunst, A. T. Cowley, and F. Masters agreed with the paper. The last two named gentlemen, whilst not in favor of elevators, considered that if wheat were handled in bulk farmers would more thoroughly clean and grade their wheat.

**MANURIAL TESTS.**—These were carried out by Mr. F. Masters under the supervision of the Branch, the results of which are shown hereunder:—

| Plot. | Manure.                                                              | Wheat Sown |                 |
|-------|----------------------------------------------------------------------|------------|-----------------|
|       |                                                                      | per Acre.  | Yield per Acre. |
|       |                                                                      | bush.      | bush. lbs.      |
| 1     | $\frac{1}{2}$ cwt. guano .....                                       | 1          | 1 23            |
| 2     | 1 cwt. guano .....                                                   | 1          | 3 27            |
| 3     | $1\frac{1}{2}$ cwt. guano .....                                      | 1          | 3 50            |
| 4     | $\frac{1}{2}$ cwt. superphosphate .....                              | 1          | 2 19            |
| 5     | 1 cwt. superphosphate .....                                          | 1          | 3 58            |
| 6     | $1\frac{1}{2}$ cwt. superphosphate .....                             | 1          | 4 23            |
| 7     | $\frac{1}{2}$ cwt. guano and $\frac{1}{2}$ cwt. superphosphate ..... | 1          | 3 34            |
| 8     | $\frac{1}{2}$ cwt. guano and 1 cwt. superphosphate .....             | 1          | 4 4             |

During the period the crop was growing 264 points of rain fell. All plots were sown on June 3rd.

#### SALT CREEK.

January 29th.—Present: 13 members and four visitors.

**WELL SINKING.**—Mr. Gale, in a short paper dealing with this subject, outlined briefly his method of sinking a well. Firstly a bore should be put down, and after being satisfied that there was sufficient water to warrant the sinking of a well, he would commence to dig. He preferred a rectangular-shaped well about 5ft. by 3ft. 6in. It was a good idea to hang a plumb line in each corner, to keep the sides perpendicular. Two measurement sticks would also be found a great help. In some cases it was necessary to timber the well as it was excavated, and in others this portion of the work could be left until after the well had been sunk. He preferred jarrah—6in. x  $\frac{3}{4}$ in. thick, or split pines made a good substitute where jarrah was considered too expensive. Care should be taken to see that the timber was perfectly dry, especially that at the bottom, as green timber was liable to taint the water. A short discussion followed the reading of the paper.

**MANTUNG.**—Mr. Lehmann read a paper from the June, 1914, issue of the *Journal of Agriculture* on "Pigs." The subject was discussed at length by members.

**YADNARIE** (Average annual rainfall, 14.09in.).

January 27th.—Present: 21 members.

The meeting took the nature of a social evening, the proceeds, amounting to £5 3s. 3d., being devoted to the Belgian Relief Fund.

**THE DIVINING ROD.**—A short paper under this heading was read by Mr. J. J. Deer. He spoke of the peculiarities of the divining rod as a means of determining the whereabouts of underground water and minerals. In the subsequent discussion Mr. W. L. Brown mentioned that the divining rod could be fairly well relied upon as a water finder, and Messrs. T. H. Pearce (Chairman), G. E. Francis, A. Spriggs, J. E. Quick, and R. H. Parbs, indorsed his remarks.

**CONSERVATION OF FODDER.**—A paper was read by Mr. F. W. Dreckow. He emphasized the necessity for conserving in good seasons such things as straw and cocky chaff to tide over periods of drought. If the straw was stacked and protected it would last for several years. Cocky chaff should, for preference, be placed in a shed, or, failing this, it should have a good covering of straw. Had more attention been paid to this during the past few years

the farmers would have now been fully repaid. In opening the discussion, Mr. T. H. Pearce (Chairman) mentioned that the advent of harvesters into the district had meant the loss of much valuable feed. He advocated stacking straw and cocky chaff. Mr. W. L. Brown mentioned that he had taken off crops with the harvester and had saved the cocky chaff by means of a carrier. Messrs. A. Spriggs, H. L. Bauer, J. E. Quick, and A. J. Hutchison agreed with the remarks contained in the paper.

## EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

### KINGSTON-ON-MURRAY.

January 29th.—Present: 13 members and four visitors.

**DRYING APRICOTS.**—The Chairman (Mr. G. J. Holmes) contributed a short paper on this industry. His experience had proved that the Royal and the Moorpark were the best two varieties. The former was the best cropper in the district, and was a firm fruit not easily bruised. Unlike the Moorpark, it ripened evenly from the stone outwards. This latter variety dried a beautiful color, and was a good cropper. He advised growers to plant a number of trees of each variety. This would do away with the disadvantage of having all the fruit ripen at the one time. He recommended building a masonry sulphur house for the treatment of apricots, leading into which a trolley line should be built, so that the fruit-laden trays could be pushed into and drawn out of the house without a person having to enter. Mr. W. Foord tabled some fine samples of whole dried nectarines; and a few peaches dried in a stone sulphur-house, were tabled by Mr. F. Merritt.

### LONG FLAT.

January 4th.—Present: 16 members.

**POULTRY-BREEDING FOR EXPORT.**—Mr. Ive contributed a paper, in which he pointed out to members the great possibilities of this industry, especially in regard to the export of eggs and the birds themselves. He mentioned that the oversea trade from South Australia commenced in 1897, and from May of that year until October, 1899, 60,000 head of poultry and 70,000 dozen eggs were exported by this State, and approximately a similar number were rejected as unfit for exportation. Australian poultry was equal, if not superior, to that from any part of the world. He deprecated the practice of exporting anything but the best, as this would tend to gradually ruin our prestige as a poultry exporting country. For egg production he had no hesitation in placing the White Leghorn first, although they were of little use as table birds. Next he would place the Black Orpington. Birds of this breed were good winter layers, produced large eggs, were small eaters, and excellent table birds. Minorcas were good layers, produced very large and white eggs, were good table birds, but were rather delicate, and were large eaters. There were many other breeds, more or less suitable for the export trade. With regard to breeding he emphasized the necessity for using only the best stock procurable, special attention being paid to the male birds. Pullets should never be bred from. The best results were obtained from mating one-year-old cockerels with second year hens. The writer then gave hints on poultry keeping. A discussion followed. Mr. Rawnsley stated that this year his Black Orpingtons had laid better than his Leghorns; owing to their better color Leghorn eggs always found a readier sale than Orpington. Mr. Ive attributed the better laying of the Black Orpingtons this season to the hardness of this breed.

### MANTUNG.

January 7th.—Present: seven members and one visitor.

**HORSE BREEDING.**—This subject was briefly dealt with in a paper by Mr. D. Stewart. Farmers, he said, were greatly inconvenienced, and often lost half a day or more waiting for a travelling stallion when they had mares to be served. Further, the service was often unsatisfactory through the mares not being mated at the right time. He therefore considered it advisable for the farmer who had five or six breeding mares to procure a stallion. This animal could be worked at various times. Care should be taken in its selection. It should

possess a good pedigree and have a Government certificate for soundness. It should be good tempered and a free worker. The best mares available only should be bred from. Some could be worked right up to the time of foaling, and others required a spell. After foaling, mares should be given as long a spell as possible. When six months old the foals should be weaned. They should be well fed and kept growing, as stunted foals took a long time to recover. It was inadvisable to break in colts before they were three years of age. Petting foals should be avoided. By careful selection, the stock could be generally improved. He favored the light draught, clean legged, active horse for this district. In discussing the paper, Mr. L. J. Pearce (Hon. Secretary) considered that as the average farmer could not afford to purchase a first-class stallion, it was preferable to procure the services of such an animal when travelling the district. Messrs. W. A., H., and D. Stewart did not think it advisable to breed horses unless an abundance of feed was available. Mr. Baker would give a colt light work at two and half years.

PARILLA (Average annual rainfall, 16in. to 17in.).

December 21st.—Present: 13 members.

**RABBIT EXTERMINATION.**—Mr. W. Rush read a short paper. He advocated destroying all shoots and bushes in the paddocks and then with a bar probing the earth causing it to run in and fill the burrows. Stumps and shoots should then be placed over the warren and burnt. Where there were windbreaks it was advisable to put down wire netting to keep the pest out of the fields. He did not think the poison cart very effective, as the rabbits did not seem to take the baits to any extent. If the holdings were wire-netted and shoots kept down the rabbits would have to go elsewhere for cover, and he believed the fox would then do a great deal towards eradicating them. In discussing the paper several members stated that they favored the poison cart. Messrs. J. Northey and R. B. Danncey thought that the use of ferrets would be effective in the breeding season. Messrs. J. Roachcock and G. E. Gregory would place poisoned water and wheat within the rabbits' reach. Wire netting the holding was generally considered to be essential.

**MANURIAL TESTS.**—The results of experiments carried out by Messrs. J. J. and C. Foale, under the supervision of a committee consisting of Messrs. A. J. Stevens, J. Till, and H. G. Johnston, are shown hereunder:—

| Plot. | Variety of Wheat. | Seed per Acre. | Super. per Acre. | Yield per Acre. |      |
|-------|-------------------|----------------|------------------|-----------------|------|
|       |                   | lbs.           | lbs.             | bush.           | lbs. |
| 1     | Marshall's No. 3  | 27             | 42               | 2               | 36   |
| 2     | "                 | 27             | 195              | 5               | 55½  |
| 3     | "                 | 60             | 63               | 6               | 16½  |
| 4     | "                 | 60             | 117              | 7               | 16½  |
| 5     | "                 | 60             | 213              | 6               | 36   |
| 6     | Federation        | 66             | 63               | 4               | 36   |
| 7     | "                 | 66             | 117              | 5               | 33   |
| 8     | "                 | 66             | 213              | 5               | 55½  |
| 9     | "                 | 30             | 63               | 4               | 19½  |
| 10    | "                 | 30             | 117              | 4               | 21   |
| 11    | "                 | 30             | 213              | 4               | 30   |
| 12    | Gluyas            | 39             | 63               | 6               | 1½   |
| 13    | "                 | 39             | 117              | 5               | 54   |
| 14    | "                 | 39             | 213              | 5               | 1½   |
| 15    | "                 | 75             | 63               | 4               | 9    |
| 16    | "                 | 75             | 213              | 6               | 1½   |
| 17    | "                 | 75             | No manure        | 1               | 51   |

The no-manure plot was sown on the edge of fallow adjoining land that had been cropped the previous year, and being half-moon shaped i.e., curved on the side adjoining the stubble, encroached about 2ft. on to the stubble land. This portion of the plot on the stubble yielded practically no wheat, and showed a very marked difference from the rest of the plot. The land chosen was of a clayey nature with strips of red sandy loam running across it. It was ploughed in 1912, left in a rough state, fallowed in 1913, and drilled on May 20th. Plots No. 1 to 16 were one-third of an acre in extent, and No. 17 was one-sixth of an acre. From seeding until harvest the plots only received 220 points of rain, and owing to seeding time being exceptionally dry a large proportion of the seed did not germinate.

## BENMARK.

December 3rd.—Present: eight members and five visitors.

**BEES AND BEEKEEPING.**—A paper on this subject was read by Mr. George Agars as follows:—"It is my intention to give a few practical hints to anyone wishing to start beekeeping on a small scale in an orchard. I advise two or three hives for a start gradually working them up to, say, 10 or 12, which would be about as many as a busy orchardist has time to attend. The first thing to do is to find out in the winter where one can get two or three good swarms in the coming spring, and, failing that, to write to some reliable beekeepers for particulars and price of nucleus hives. There are quite a number of hives on the market, but there are two sorts used principally in Australia—the Langstroth and the Bolton, both of which are good. There is also a hive used in South Australia known as the South Australian hive, which is a modification of the Langstroth, but is not so well made, not having the dovetailed corners. This hive is not so handy as the latter, and is harder to manipulate, as the covers fit down over the top of the body, instead of standing on top, as in the Langstroth, and are harder to get on, especially if they become warped. Also, in this hive, the bees are liable to build a lot of burr comb on the top and between the frames, which is a constant nuisance when looking through the hives for taking honey. A perfect hive should give absolute control over the combs, so that they may be easily removed and replaced without jarring or doing anything else to annoy or excite the anger of the bees. It should be simple in construction, and have as few parts as possible. All parts of the hive should be so accurately made as to be inter-changeable. In this way honey, brood, combs, &c., &c., can be transferred from one hive to another. This is important in an apiary, and if hive parts are not inter-changeable much needless labor is involved. Hives are made in two sizes—the eight and the 10 frame, both of which are equally good. I prefer the 10 frame, as it gives more room for storing honey, and does not need a following board, as in the eight frame. However, this is a matter of no great consequence, as long as the hives are all the same size. The best frames for the Langstroth hives are the Root-Hoffman self-spacing; all that is necessary is to push them together in the hive, and the shoulders space the frames correctly. The comb foundation is easily fixed into them with a 'Daisy' roller; they are very strong, and do not come to pieces when being handled, and in the extractor. All the packing a hive of bees fitted with these frames requires to travel over the roughest roads is to press them together and place a wedge behind them, and they are immovable. The next thing required is a few pounds of comb foundation for use in the new frames, also a reel of wire to fix them. The foundation is pressed wax sheet, so made as to give the bees a start to build their comb, and to insure that they build it perfectly straight along the frames; otherwise they are liable to build them across the frames, and so stick them all together, and prevent their easy removal. By using comb foundation one can regulate the number of drones in a hive, and get more worker-cells built, and consequently more workers in the hive. Always use full sheets of foundation in the brood-chamber, or lower hive, and just narrow strips, 2in. wide, in the honey-chamber, or top hive. The reason for this is that, whereas in the brood-chamber one wants all the worker cells one can get, in the honey-chamber it does not matter whether the bees build worker or drone cells, as long as they build them straight along the frames. Of course, some drone cells are necessary in the brood-chamber, and to insure these all one has to do is to cut out a small piece of some of the frames when fitting in the foundations; the bees will fill the space thus left with drone cells. Before we proceed to the handling of frames, we will consider the tools necessary for the work. First and all-important is a good smoker; next, some sort of a hive tool, which may be an ordinary screwdriver, a putty knife with a stiff blade, or a special tool made for the purpose. Such a tool is described in the 'A.B.C. of Bee Culture,' by Root. Now, to proceed to the actual handling. First, do not try to handle bees on a dull, cloudy day or late in the afternoon. Choose a fine, sunny morning, if possible, or early in the afternoon. When going up to the hive always keep out of the flight of the bees—that is, go up to the side or back of the hive, not the front. Have the smoker ready, and blow a puff of smoke into the hive entrance. Then wait a few seconds, and proceed to lift the cover with the tool by prizing it up just a little—not enough to allow the

bees to escape, but sufficiently to allow a little smoke to be blown under it. Then quietly lift the cover off and place it on the ground, or use it to sit on if the hive is very low. Then take hold of the mat at the nearest end, and gradually lift it, at the same time blowing some smoke on to the bees; then, with the aid of the knife, proceed to prize the frames apart and lift them out for examination. If the bees seem inclined to resent this, give them some more smoke, which will generally quieten them. But if the day is bad, and they are still fractious, the best thing to do is to close the hive and leave them alone. In fact, whenever bees show fight, always walk away quietly and do not strike at them, and they will usually quieten down. When handling, let the movements be quiet and deliberate, not jerky or quick, as this will excite the bees. The reason for handling the frames in the brood-chamber, especially in the spring and early summer, is to find out if the queen is laying all right, and to get an idea as to whether they are likely to swarm, and when. If the queen is doing her work, one will find the eggs laid, one only in each cell, and that right at the bottom; whereas, if she is not, or is dead, or injured, there will either be no eggs, or else one of the worker bees will be trying to take her place, and eggs will be found, two in some cells, three in another, and so on, indiscriminately, and sticking to the side of the cells, half-way down. One will also notice in a case like this that the bees are sluggish, and not so numerous as when the queen is working properly. Give the bees another queen at once, or give them the chance of providing themselves with one. This may be done by removing one of the centre frames from the hive, and exchanging it with one from another hive where the queen is at work, and there are sure to be newly-laid eggs—that is, eggs not three days old. If this is done, the bees will immediately rear a queen for themselves. Be sure and brush all bees off the frame before putting it into the new hive. Another reason for examining the frames is to see if the bees have built any queen cells; if so, they will soon swarm. If the ends of the cells are still open, that is, not capped over, it may be some time; but if the queen cells are capped over, they will swarm within a day or two; they usually swarm within about three days after the cells are capped. When one finds this, one should go through the frames, and cut out all but one of the best; otherwise more than one queen may be hatched out, and that means two swarms or more, which unduly weakens your hive. Swarming cannot be prevented altogether, as it is the natural instinct of bees, caused principally by their hive becoming overcrowded, and not leaving room for them to store honey. One of the best means to prevent swarming is to give the bees plenty of room in the spring. Take out all surplus honey left over from the winter, and generally clean up the hive. The bees, before they swarm, always send out scouts to find a new home to which they may go; but they always settle on some bush, or tree, or other object near their old home, while waiting for the scouts to return to let them know where to go. So the beekeeper has the chance of catching them before they finally clear out. The best way to do this is to shake them into a box, which should be kept for the purpose, and cover them with a sheet until the evening. (They do not usually clear out for their new home until the morning after swarming.) As soon as they are in the box, turn it upside down on a bag, being careful to place a piece of wood or other object under one end, to allow all the bees to get into it, then cover them with a sheet. Shift the hive from which they emerged a few feet to one side; into a new place; then place the new hive in the spot where the old one stood. Just about sundown bring the box containing the swarm, or the best part of them, and shake some of them on to the front landing-board of the new hive; when they start to go into it shake the balance, and leave them for the night, removing the box; and in the morning they will be found in their new hive. To make sure of their taking to the new hive, it is a good plan to take a frame of brood from another hive, and having brushed off all the bees, place it in the centre of the new hive, along with the empty frames already in it. This will help to keep the bees from going away, as they very seldom abandon brood or eggs. The beginner with bees should provide himself with a good hat and veil, as a protection against stings. An old straw hat, with a stiff brim, and some colored mosquito-netting sewn round it, does very well.

**WILKAWATT** (Average annual rainfall, 16in. to 17in.).

January 30th.—Present: 14 members and one visitor.

**CARE OF HORSES.**—In dealing with this subject in a paper Mr. C. Sorrell outlined his method of building his stables. Every horse, he said, should have its separate stall. When feeding at morning, midday, and evening they should be tied up, but loosed when fed at night and given access to an adjoining paddock. They should be watered before being fed, and be well groomed every morning. It was inadvisable to give them a drink immediately before starting the day's work. Members discussed the paper and generally agreed with its contents.

**WAGON DRAUGHT.**—Mr. H. H. Brooker read a paper as follows:—The influence of the height of the wheel on the draught of farm wagons has been the subject of recent experiments. Practical tests were made in a series of trials over macadam, gravel, and dirt roads in all conditions, and also over pasture, stubble, and cultivated paddocks, with a net load of 2,000lbs. in all cases. Three sets of wheels were tested as follows:—Standard, front wheels 44in., rear wheels 55in.; medium, front wheels 36in., rear wheels 40in.; low, front wheels 24in., rear wheels 28in. The results obtained and conclusions reached were, in brief, as follows:—For the same load, wagons with wheels of standard height drew lighter than those with lower wheels. The difference in favor of the standard wheels was greater on road surfaces in bad conditions than on good surfaces. Low wheels cut deeper ruts than those of standard height. The vibration of the tongue is greater in wagon with low wheels. For most purposes wagons with low wheels are more convenient than those of standard height. Wagons with broad tyres and wheels of standard height are cumbersome, and require more room in turning. Diminishing the height of the wheel to from 30in. to 36in. in front, and 40 in. to 44in. in the rear, did not increase the draught in as great proportion as it increased the convenience of loading and unloading the ordinary farm freight. Diminishing the height of the wheels below 30in. in front, and 40in. at the rear, increased the draught in greater proportion than the convenience gained. On good roads, increasing the length of the rear axle, so that the front and rear wheels would run in different tracks, to avoid cutting ruts, did not increase the draught. On sod, cultivated ground, and bad roads wagons with the rear axle longer than the front one drew heavier than one having both axles of the same length. Wagons with the rear axle longer than the front one required wider gateways and more careful drivers, and were, on the whole, very inconvenient, and not to be recommended for farm use. The best form of wagon was one with axle of equal length, broad tyres, and wheels 30in. to 36in. in height in front, to 40in. to 44in. behind.

**LAMEROO.**—The Poultry Expert (Mr. D. F. Laurie) addressed the members on poultry matters generally, dealing mostly with the growth of the chick whilst in the shell.

**LONG FLAT, January 25th.**—The President (Mr. J. G. Forster) gave a short address on "How to determine the ages of horses, cattle, and sheep." A discussion followed, in which several members mentioned that they had known cases where horses of, say, six years, had mouths identical to those that were generally possessed by eight-year-old animals. It was generally agreed that the teeth of horses which were fed on short feed grew to a greater length than the teeth of those fed on long feed, or grazed on coarse feed.

## SOUTH AND HILLS DISTRICT.

**BLACKWOOD** (Average annual rainfall, 27in. to 29in.).

November 16th.—Present: 17 members.

**MANURES AND MANURING.**—Mr. A. K. Ashby read a short paper dealing with orchard manuring in this district. He favored stable manure, which should be spread amongst the trees in the early spring; but in some instances, where the soil was too soft to admit

of carting in the spring, it should be spread in autumn. In the latter case, a good growth of dandelions and other weeds which tended to prevent the earth washing away from the trees and also enriched the soil when ploughed in, would be secured. He would not manure the trees until they were in bearing, and then about 10 tons of stable manure to the acre should be used, or failing that, 7 tons of bonedust. A crop of peas sown at the end of May or beginning of June between the trees and ploughed in in September would be very beneficial as a green manure. Mr. A. W. Magarey also contributed a paper on the subject of manures. "In considering the best manure to use we must take into account the nature of the soil and the crop to be grown. If, for instance, the soil is deficient in phosphoric acid, an application of ammonium sulphate would not benefit the crop; but, on the other hand, if the soil lacked nitrogen the result would be of great benefit. Then, again, if we wished to grow peas, we would not use a nitrogenous manure, but cabbages would derive great benefit from application of such a manure. The sources of potash are—Muriate of potash, containing 1366 K per ton; sulphate of potash, containing 1164 K per ton; kainit, containing 268 K per ton; wood ashes, containing 20 to 110 K per ton. Potash manures increase the quality and flavor of fruit, and particularly the sugar contents of the fruit. They also help to build up the woody tissue. The sources of phosphoric acid are—Bonedust or bone super., superphosphate, Thomas phosphate, guano super. Bonedust, bone super., and Thomas phosphate are the best forms to use when planting young trees, and they should be worked into the lower layers of soil. Phosphates tend to fruitfulness and early ripening. The sources of nitrogen are—Nitrate of soda, 16 per cent. N; sulphate of ammonia, 20 per cent. N; soot, 2 per cent. N; blood, 12 per cent. N. Nitrogenous manures tend to increasing the growth of wood and foliage and the rind of the fruit. Nitrate of soda is the most direct in its action; but, on the whole, ammonium sulphate gives the best results. The sources of lime are—Calcium oxide or quick lime, calcium sulphate or gypsum. Lime in itself is not a manure, but acts on the physical condition of the soil, setting free other compounds, making them available as plant food. Lime is particularly useful in heavy clay soils, rendering them more friable. It is also said to help to prevent the falling of stone fruit at the stoning period, more especially with apricots. Stable manure, when well rotted, contains  $K_2O$ , 10lbs to 12lbs.; N, 8lbs. to 12lbs.;  $P_2O_5$ , 5lbs. to 11lbs. per ton. On the whole, this is more suited to vegetables than to either fruit trees or cereal crops as it is liable to cause rather rank growth, especially with the latter. Like green manuring, it is very valuable in improving the physical condition of the soil. There is some difference of opinion as to when to apply the manures; but, as a general rule, the less soluble manures should be applied early in the winter, especially such as bonedust, blood, lime, farmyard manure, and even superphosphate; but the more soluble manures give better results if applied later, especially in wet years. I have seen splendid results with wheat crops that have been sown with superphosphate and then in September dressed with  $\frac{1}{2}$  cwt. ammonium sulphate per acre. In this district, in ordinary years, most of the hay crops look as if they were short of nitrogen owing to the excessive wet. The third point to consider is how to apply the manure. Some advocate spreading it around the trees and hoeing it in; others, fixing a box to the plough and letting the manure run into the furrow as the plough goes along. The quantities to apply according to the size of the tree are—Potash, 1lb. to 3lbs.; phosphates, 3lbs. to 10lbs.; nitrates, 1lb. to 3lbs.; lime, 1 ton to 2 tons per acre; farmyard manure,  $\frac{1}{2}$  cwt. to 4cwts. per tree."

#### INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

December 30th.—Present: six members and one visitor.

**FRUIT ON THE FARM.**—A paper was contributed by Mr. H. T. Martin on this subject, in which he urged all farmers to cultivate fruit on their holdings; at least sufficient for household requirements. The site selected should be a flat piece of land with a good natural drainage or a slope facing the east. He would plant the trees about 30ft. apart. This would prevent overcrowding of the roots and branches; allow the sun to reach all the fruit, and give plenty of room for working. Sufficient room should also be left between the outside rows and the fences. The land should be thoroughly worked before planting. It was advisable when ordering the young trees to obtain varieties that yielded fruit at the different periods of the year. They could be obtained for about 75s. per 100. This would ensure always having ripe fruit available. The holes should be taken out not less than 2ft. deep and 3ft. square, and after a good airing should be filled in to within 9in. of the top. They should be dug before the trees were

obtained. When planting the ends of any bruised roots should be cut, and the longer ones spread out. The trees should be planted at the same depth that they were growing in the nursery. They should then be cut back to the desired height and their growth carefully watched. When pruning the outside bud should be left and the trees gradually trained to a wineglass shape. When well established only ordinary judgment was necessary to keep the trees in good order. By the third year portion of the early bearing varieties should be in bearing; in the fourth and fifth year sufficient fruit for the household should be available, and by the eighth year there should be £10 worth of surplus fruit from an acre of trees. He emphasized the necessity for erecting a good fence round the fruit garden. This should be about 4ft. high, the top three wires being barbed. The bottom wire placed about 2ft. 8in. from the ground, should be plain, of No. 6 or 8 gauge. Attached to this should be wire netting, buried 4in. into the ground. Members discussed the paper, and were generally of the opinion that fruit-growing should be given more attention by farmers.

#### MACGILLIVRAY (Average annual rainfall, 9in. to 20in.).

January 27th.—Present: five members and three visitors.

**FARM MANAGEMENT.**—A paper under this heading was read by the Hon. Secretary (Mr. J. E. Johnston). Good management in farming, as in all things, stood for success, he said. Fallowing was a most important item, so also was the conservation of water and fodder. Fallow should be ploughed to a depth of not less than 5in., and followed by cross harrowing. This should be finished by the end of August. With reference to the conservation of fodder, he considered that at least enough hay should be cut each harvest to tide over until next harvest. He preferred wheaten to oaten hay. He would also have a stack of straw. He did not advocate conserving cocky chaff. Every farmer should, if possible, sink wells, and not rely solely on dams, as a permanent water supply was very essential. He advocated keeping a few cows, pigs, sheep, poultry, &c., at least sufficient for household requirements. Machinery when not in use should be kept under cover, woodwork painted, and such things as plough discs, &c., given a coat of neatsfoot oil to prevent rust. Harness should always be kept in good repair, and have an oiling at least four times a year. Stables should be built facing the east, and be divided into separate stalls, and each animal's harness should be hung in his stall. This would ensure each horse always having the same harness. No fences should be less than 3ft. 4in. high, and he preferred to have them of six wires—five plain and one barb (on top), with wooden posts about 1 chain apart, and a tee iron post in between each. He emphasized the value of keeping a set of books to keep records of all business transactions. In discussing the paper most members disagreed with the writer's remarks *re* conservation of cocky chaff. They mentioned that cocky chaff mixed with a little pollard was a good substitute when better feed was scarce. Mr. Johnston replied stating that when feeding cocky chaff he had had to add  $\frac{1}{2}$  bush. pollard and  $\frac{1}{2}$  bush. oats per horse, and this was just as expensive as giving 40lbs. hay chaff per day.

#### MEADOWS (Average annual rainfall, 35.52in.).

November 3rd.—Present: seven members.

**FARMYARD MANURE.**—Mr. W. Phillips read a paper on this subject. The following is extracted therefrom:—"The value of stable manure in this cold district for growing green feed such as barley, rye, and vegetables in the winter, and in the summer for maize, kale, rape, and chou mollier, also for a mulch around fruit trees, is well known. It opens up clayey soil, and makes it easier to work. It is one of the most complete manures for any crop, and for this reason should receive more care than it usually receives. Some farmers put the manure straight out on to the land, and plough it in, and the usual result is a fine crop of weeds, such as sorrel. Then again some cart it into the paddocks and put it in heaps and leave it for the fowls to spread, and the result is a patchy crop, very rank where the heaps were. I consider that after manure has been left unprotected from the sun for a few months, it is very little better than sawdust. I prefer to allow it to rot before using it, unless it is to be used for a cut of early green feed,

such as barley. I have had good results from ploughing the manure in straight from the stable for this purpose. For potatoes, I prefer well-rotted manure, unless it is ploughed in a few months before planting, and in the meantime worked well. The method I adopt in handling the manure is as follows:—I have four posts in a square of 10ft., and one rail on top on three sides, the front being open. I have rough slabs and other timber standing up inside of these rails. The manure is taken from the stable in the wheelbarrow, and thrown into this square, spread evenly, and well trodden down. During the winter I put a few sheets of iron over the manure to keep the heavy rains out, only letting in a little now and again to help the rotting process. Some time ago I dressed some potatoes with well-rotted manure, manure fresh from the stable, and manure that had been exposed and scattered about all the winter. I put in 1cwt. of potatoes, with three drayloads of each manure, and the results were:—From well-rotted manure, 19cwt. of potatoes; from fresh manure, 3cwt.; and from the exposed manure, 1cwt. of potatoes (similar to marbles)."

#### MORPHETT VALE (Average annual rainfall, 23.32in.).

January 19th.—Present: 10 members and one visitor.

PROFITABLE FARMING ON SMALL HOLDINGS.—Mr. A. Anderson contributed a paper under this heading. He pointed out that whereas the big farmer could rely solely on his wheat harvest, wool clip, or sale of stock for his income, it was advisable that the man on the small holding should adopt one or more side lines to increase his revenue. He would keep a few cows, pigs, and poultry, all of which, if properly attended to, would be found profitable. It was also a good plan to set aside, say an acre of ground, for cultivating sufficient fruit and vegetables for household requirements. In the subsequent discussion Messrs. Sprigg and Perry both emphasized the value of one or two side lines, especially in seasons such as this

#### MOUNT COMPASS.

September 12th.—Present: eight members and one visitor.

DAIRYING.—Papers on this subject were read by Messrs. L. Roediger and S. Simons. Mr. Roediger said the provision of a suitable food supply was a point of the utmost importance to the dairyman. A sufficiency of lime in the soil was a necessary factor in the health of the cows, as was also the provision of shelter. If rugs were used, they should be removed at frequent intervals. Animals affected with lice should have sweet oil poured on to the backbone. For milking purposes, the merits of the Jersey breed could not be overlooked, but the Jersey-Ayrshire cross provided the most suitable cows for Australian conditions. He urged the wisdom of delivering milk to the factories, and strongly supported a system of compulsory grading of cream. He had had two years' experience with a milking machine, and had found it very satisfactory. Dealing with pig-raising, as an adjunct to dairying, he expressed a preference for the Yorkshire-Berkshire cross. The pigs should not be allowed to breed until they were 10 months or 12 months old, and a sow which did not produce an average of eight or more at each farrowing was not profitable. The young pigs should be weaned when they reached an age of six weeks or eight weeks. Subsequently they should be fed on milk and pollard, grain being gradually added to their diet. Barley, wheat, or peas should be fed for topping off. A mixture of barley, wheat, oats, and peas, with skim milk, produced the best bacon. For market, porkers should weigh from 60lbs. to 80lbs, and baconers 130lbs. to 140lbs. The sow should not be allowed to become too fat, a liberal amount of exercise being essential. Immediately the young were weaned, the sow should be again put to the boar. Sties should be constructed with brick floors, laid with cement. Draughts should be carefully guarded against. Mr. S. Simons said the production of summer fodders was essential to success in dairying. Well-drained land could be planted with maize, the seed being sown in every third furrow behind the plough. A good soaking once each week would ensure rapid growth. Chaffed and fed to cows, this crop was an excellent milk-producer. With proper care, lucerne would stand cutting six or seven times per year for seven years, and produce up to six

tons to the acre at each cut. The class of cow he preferred was the Jersey-Short-horn and Jersey-Holstein cross, or a second cross between these two. Notwithstanding that, he would not discard any cow of good frame, with a large, well-formed udder, and bright eye. The calf should be taken from the cow immediately the former could walk; the cow would then not hold back her milk, and the calf could more readily be taught to drink. A bail provided for every cow would be found to more than compensate for the outlay involved. The floor of the shed should not slope more than was necessary to ensure effective drainage. The continuous manger was the most economical method of feeding. The writer then described the method of milking he practised, and discussed the value of milking machines. He strongly recommended the provision of extra supplies of feed in cold weather, in place of rugging the cows. Members discussed the paper at length.

PORT ELLIOT (Average annual rainfall, 20.33in.).

November 21st.—Present: nine members.

**FRUITGROWING.**—A paper under this heading was read by Mr. E. Lay. Fruit trees, he said, grew equally as well on hilly slopes as on level ground, but they should always be sheltered from prevailing winds. If there was no natural breakwind a row or two of pines would serve admirably. If the garden was on a slope it was an advantage if it faced the east, as then the trees would have the benefit of the early morning sun. If the soil was stiff and clayey, or if citrus trees were planted, good drainage was necessary. The ground should be well worked, going as deep as possible without bringing up inferior soil to the surface. He would intermingle different varieties of any one sort of fruit. Thirty feet should be left between each tree to give sufficient room for working the orchard. With regard to fertilising, he considered that once the young trees were well established, no manure was necessary for five or six years, and then farmyard manure, bone dust, and superphosphate would be found best. The manures should not be placed too close to the trunks of the trees. Farmyard manure should be spread in autumn and ploughed in with the first winter rains. Fertilizers of a more soluble nature should be applied at the end of the winter or in the early spring, followed by light cultivation. Five to 10lbs. of manure, according to size of the tree, should be sufficient. The orchard should be ploughed in the autumn, left open to the winter rains, then again ploughed in September, and harrowed down. During the summer frequent cultivations, especially after rain, would be most beneficial. In discussing the paper Mr. Brown stated that this district was suitable for apples, pears, peaches, and almonds. Mr. H. Welch urged members to increase the size of their orchards, and produce enough fruit to warrant the establishment of a factory for fruitpacking and jam-making in the district.

**BLACKWOOD, December 14th.**—A demonstration in summer pruning was given by the Government Horticultural Instructor (Mr. Geo. Quinn), at Mr. W. L. Summers' orchard, and at the Government Experimental Orchard, in this district.

**BLACKWOOD, January 18th.**—Mr. W. L. Summers gave an address on the work of reclaiming the Murray River swamp lands.

**INMAN VALLEY, January 27th.**—Mr. H. J. Dennis gave an address on sheep-raising and dairying. It was the general opinion of members that sheep were the more profitable on large holdings, but that dairying would be the more remunerative on small holdings of, say, one section or less. Mr. Gray stated that he had netted £90 annually from 10 cows on a small holding, and in addition £70 to £80 from pigs. Mr. Dennis estimated that one section would carry 10 head of dairy cattle or 80 ewes and 60 lambs, and Mr. A. J. Meyer (Chairman), thought that a holding that would carry that number of lambs and ewes would carry 15 dairy cows.

**IRONBANK, November 28th.**—Mr. R. Coats contributed a paper dealing with the export trade in poultry, in which he expressed a preference for the Indian Game crossed with either the Buff or Black Orpington or Wyandotte.

**MANURIAL TESTS.**—Mr. W. Salter conducted manurial tests on cabbages. Plots of one-tenth acre in extent were dressed with manure as follows. Plot No. 1, bone and super. 28lbs., sulphate of potash 7lbs., with a top dressing of 20lbs. nitrate of soda, about a fortnight after planting out. Plot No. 2—Bone and super. 28lbs., and 7lbs. sulphate of potash, top dressing of 20lbs. of nitrate of soda fortnight after planting out, and second dressing of 20lbs. nitrate of soda about four weeks later. Plot No. 3—Bone and super. 28lbs., and sulphate of potash 7lbs. The average weight of the cabbages on each plot were:—Plot 1, 7lbs.; plot 2, 5½lbs.; plot 3, 4½lbs.

**IRONBANK, January 23rd,**—The Branch was visited by Mr. George G. Nichols (Secretary Advisory Board), who addressed members on Bureau matters generally.

## SOUTH-EAST DISTRICT.

**KYBYBOLITE** (Average annual rainfall, 22in.).

December 22nd.—Present: seven members and two visitors.

**POINTS FROM THE SEASON 1914.**—The following paper was contributed by Mr. E. A. Alcock:—"In the past it has been a common saying that a drought could not affect the States to the same extent that it did in 1902 or 1895-97, but as far as I am able to ascertain the effect was not so far reaching, as this season it has been found necessary by the different Governments of the Commonwealth to pass special legislation to relieve the distressed, and to make provision for the coming season. Throughout this State 1914 is the driest season on record, and with few exceptions all stations recorded less than half the normal fall, and the 'useful rainfall,' i.e., from April-September, in many places only 2.5in. were recorded, and it is officially estimated that from 700,000 to 800,000 acres sown either failed to germinate or were fed off early in the season. *Time of Sowing.*—The first point to which I would like to draw attention is the time of sowing. For Kybybolite district the ideal month for sowing wheat or oats for hay or grain is May; whilst barley and peas are better sown later, in June or early in July. Early sowing has many advocates, who claim that they have a chance to re-sow should the early seeding prove a failure, less risk of losing time through wet weather; if the crop should grow too rank it can be fed off with stock. The disadvantages were the risk of malting, difficulty at harvest time in handling a rank crop, and also a danger of late frosts or early hot winds, thus affecting the grain returns. We have no guarantee with regard to the season, and we increase the risk by late sowing, and there is a danger of loss of time through wet weather. At this time of the year the ground is wet and cold, and the young plants make poor growth, are weak and unhealthy, and unless a favorable spring follows, the returns are unprofitable. The large number of failures this season are largely due to sowing out of season. The difference between thick and thin sowing was very marked this season, particularly where graded and non-graded seed were used in the same field, 30-40lbs. of graded seed gave a better return than 60lbs. of ungraded. The thinner seeding gave the plants a chance to stool out, and as the seed was graded every grain grew, producing a strong healthy plant, whilst in the thicker sowing a number of short, spindly plants grew for a time, and then gradually died, all the time robbing the stronger ones. It was very noticeable in every district this season, where two paddocks were sown, one of which was under fallow last season, and the other either crop or pasture, that the results were all in favor of the fallow that was well worked. In many districts they were only able to cut their hay from that portion fallowed, and in the drier districts it was only from the fallow that any returns were obtained. I would like to call attention to the benefits derived from rolling in dry seasons. It is not a general practice to roll in this district, as our soils melt down with the first heavy rain that falls, but this implement might be used with advantage to consolidate and compact the soil, thus improving the seedbed, even if it was necessary to follow with the harrows immediately afterwards to loosen the surface. To see the effect of consolidating the seedbed in the field, any observant person will have noticed

those rows down which the drill wheel has passed the seed germinates better, and very often they can be seen right up to harvest time, as this season they were very marked, both in the autumn and also the spring-sown crops. It is in dry seasons that the full benefit derived from the use of phosphates is borne out; as in every instance this season where a plot was sown with manure alongside a similar plot without the manure, it was not necessary to have a peg in the fence to mark the place where the super. was shut off. It is often said that heavy dressings of super. burn the crop in dry seasons, however this season several plots were sown with as much as 3cwt. of super. per acre, and in no case did burning take place; instead, the lighter the dressing the lower the return, and vice versa. Perhaps it would be interesting to mention the effect of lime on the growth of wheat and oat crops this season. In every instance where lime was applied the plants looked much healthier, brighter in color, stood better, with more abundant foliage, and were much better headed than those not limed. The real value of straw stacks was not fully realised by many farmers until this season. Time and again it has been pointed out that no provision is made for a lean season. However, to guard against such it will be necessary to save everything that may be used as fodder, such as straw and cocky chaff, and also conserve green stuff as ensilage. Whilst May is the ideal month for sowing the bulk crop, earlier sowing should be made during the month of March or as early as February if sufficient rain falls. Successful results have been obtained at the Kybybolite Experimental Farm by sowing rye as early as possible (February or March), and then crossing with Algerian oats a month or six weeks later. A block sown thus (50 acres) proved invaluable this season. At the same time it is well to point out that it is necessary to provide some dry matter in addition, and if this is not possible, to give the stock access to a stack of straw—it is necessary to cart it out as loose straw or chaff it up and place in troughs. The necessity for green food during the summer months is felt by all stock owners every season, and even more so in a dry one, and although a larger area than usual of such crops as kale, millet, and sorghum was sown this season, the total area is comparatively small compared to the stock kept. October is the best month for sowing these crops, but later sowing may be made in favorable seasons. Kale sown in October should be ready for feeding in January, and millet and sorghum a little later, and in years of plenty the latter can be cut and made into ensilage, and if properly cured will keep almost indefinitely. The most valuable forage crop of all is lucerne. Where this can be grown (and there are not many places that a small plot, if properly attended to, cannot), it will prove a valuable asset in an ordinary season, and more so in a dry one. It should not be beyond the means of any farmer to have a small plot sown near his windmill, but it is well to remember that irrigation, to be carried out successfully, requires a constant and ready supply of water, so that it is better to have a small plot, say about quarter of an acre. This can be watered from the windmill and manured with the manure from the stable. It is also a good plan to sow those fields under crop with a light seeding of lucerne to provide a picking for the stock when the crop is taken off. In conclusion, the main points are to be prepared for a dry season by sowing a field early in the season for green feed, and if not wanted this can go to help fill the silo; also prepare for the dry months of the year by sowing an area with kale or sorghum, and at seeding time have the land in good order and sow at the right time; not too early, nor leaving it till the winter has set in. Use only clean, graded seed. After seeding is completed, attend to the fallowing for the coming season; after harvest have all the straw and cocky chaff stacked and secure against the weather and stored for future use."

December 12th.—Present: 16 members.

**SUMMER FODDER CROPS.**—This subject was dealt with in a lengthy paper by the President (Mr. R. P. Pritchard). Maize, millet, and sorghum, he said, were the three main summer fodders. He had tried many varieties of maize, and had had best results from the Longfellow variety. Hickory King had also given good results. In selecting maize for fodder it was important to remember that while some varieties were remarkable for their grain yield, others were prolific in succulent foliage. It was therefore obvious that a variety of the latter class should be chosen for fodder purposes. Some Longfellow maize, which had only been sown

11 days, was now showing 2in. above the ground. Although he had not grown millet prior to this season he had seen excellent results obtained from the Japanese variety in this district. Sorghum also grew very well here. He was trying amber cane. All the plants mentioned thrived with a minimum of rain, and produced an abundance of fodder. It was advisable to plant the seed for these crops wide enough apart to work a horse hoe in the rows to keep down the weeds. It was not too late to sow these fodders even now if the ground was suitable. He emphasized the fact that not nearly enough summer crops were sown in this district. If more were sown there would not be the number of dry stock in this district at certain periods of the year when the cows were now dependent on the natural grasses only. He had also planted some cattle pumpkin as an experiment. This was to be cut up and fed to cattle with the chaff. Mr. Sassanowsky agreed that the growing of summer fodders was not given sufficient attention in the South-East. He did not think that their present system of cultivation, especially for maize, was the best; Mr. Watson concurred. In reply to a question, the writer of the paper stated that he ploughed in mid winter. He did not consider that the loose surface sand would cut down the young plants. Reference was made to the wonderful growth Mr. Major's lucerne had made this year, although it was growing on a dry hill. Mr. Major informed the gathering that he had ploughed to a depth of 4in., harrowed thoroughly, and sown with 12lbs. Hunter River seed to the acre. It had been in two years. During the first year it made very little progress, but he then put the spring tooth into it, followed by the harrows.

---

NARACORTE, January 20th.—VETERINARY LECTURE.—The Government Veterinary Lecturer, Mr. F. E. Place, B.V.Sc., M.E.C.V.S., visited the branch. In the morning he gave a practical demonstration on the horse, and in the afternoon he addressed members on lameness in horses. Many questions were asked and answered, and much valuable information was gained through the visit.

Camel Team, Oodnadatta.

## INQUIRY DEPARTMENT.

---

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

### STOCK INQUIRIES.

Replies supplied by Mr. F. E. PLACE, B.V.Sc., M.R.C.V.S., Veterinary Lecturer.

"P.," Bews, asks treatment for mare which has been ill for about 20 days. She is hollow, and stiff in hind legs, does not lie down, but has fair appetite; left udder is swollen, and there is also swelling under belly; heart beats very fast; there is slight running at nose, and breathing is irregular.

Reply—The symptoms of influenza pneumonia, connected with invasion of blood worms, chance of recovery not too bright. Have a dozen powders made up at the chemist's, each to contain 4grs. of iodide of arsenic and 10grs. of sugar of milk, and put a powder on the tongue morning and evening. Also get  $\frac{1}{2}$ oz. of sulphate of quinine and mix a teaspoonful with a little molasses and smear on the tongue once a day. If the mare recovers she should not have any work for several weeks.

"H. R. H.," Laura, asks treatment for pony stallion which, on change of feed from hay to lucerne, commenced to fall away, and has not picked up. Is stiff over loins, and unable to do easy journey.

Reply—The symptoms point to digestive upset, and probably a 4-dram physic ball would do good; but if the lungs are in any way affected it would not do good; so, instead, it would be better to give 10 drops of tincture nux vomica and 10 drops tincture arsenicum alternately every three hours for three days, and then morning and evening for three more. Give a little cocky chaff with the lucerne.

"G. C. J.," Adelaide, inquires as to the use of laudanum for doctoring stock.

Reply—Laudanum is a good painkiller for stock, but rather expensive. The dose for a horse ranges from a dessertspoon to two tablespoons.

"J. S.," Yadnarie, asks cause of horses' hair being rough and dry at root of tail and on rump. They are fed on cocky chaff and corn.

Reply—The symptoms are those of whip worms, which live in the hinder bowel. They can generally be dislodged easily by an enema of a quart of warm milk with two or three tablespoons of turpentine in it. The horses would also probably benefit by having a tablespoonful of sulphur once a day in the feed for a fortnight or so. The stivering coat can be laid by a cloth damped in kerosine.

"D. A. C.," Spalding, forwards gravel taken from stomach of horse which died from no apparent cause. The owner is puzzled as to how horse swallowed the gravel.

Reply—The gravel sent was most probably ingested while the animals were drinking, and would be found almost pure in the U bend of the bowel just as it leaves the stomach. It would be almost impossible to diagnose its presence without the X rays, but horses suspected to be affected should be put on bran mash only for three days. Afterwards 10 drops of tincture nux vomica morning and evening will help to clear it if given for a week or 10 days.

"A. W. T.," Karoonda, has horse with two egg-shaped lumps on either side of the windpipe behind the jawbone, the size of small hen egg. They are not painful, but the horse is not doing well. He asks treatment.

Reply—Enlarged thyroid glands. They can be felt in all horses in this position, but much smaller; they are regulators of nutrition, and their enlargement points to want of certain food constituents. Rub a little blue mercurial ointment into the lumps once a day for a fortnight, and give on the tongue twice a day two tablespoonfuls of syrup of phosphate of iron for the same period; also once a day in food, a small handful of bonemeal or a pint of limewater.

"J. E. C." asks how to drench horses.

Reply—To drench, slip a loop over the upper jaw behind the tusks, back the horse into a corner, throw the line over a beam and raise the head just sufficient to give a fall on the back of the tongue. Failing the beam, put the loop over the prong of a fork, or tie it on to a broom handle and raise the head as before. Stand in front of the off shoulder, on a box if necessary, put the left hand on the tongue and tickle the roof of the mouth with the fingers; put the neck of the bottle into the mouth just in front of the molar teeth and let it touch the roof; let a few drops of the drench fall on the tongue, and natural swallowing will follow. When this starts give a wineglassful, let it be swallowed, another, and so on to the end; do not force the drench into the mouth, and above all, let the head down at once if the horse coughs, and do not continue to drench.

"W. F. S." asks how to treat mare which is in splendid condition, but in spite of grooming her hair stands up.

Reply—Cause is probably seasonal and possibly worms. If, after grooming, she is lightly wiped over with a cloth just damped with kerosine, it may improve matters. Try a tablespoonful of the following powder once a day in her food for two or three weeks:—Sulphate of iron, sulphur, saltpetre, black antimony, gentian, Epsom salts, of each  $\frac{1}{4}$  lb.; sugar, 2 lbs.

"E. C. S." has filly which one day, after drinking, suddenly fell down and could not get up. She was helped to her feet, and could just walk when steadied. When down she injured herself, and on the fourth day her near eye wasted and finally came out; a scum accumulated over the other eye, and she is now quite blind. Her legs became swollen, but all except near hind leg responded to treatment with hot water. Swelling on near hind leg has broken half-way between hock and fetlock. He seeks advice.

Reply—The symptoms point to blood poisoning by toxins formed by blood worms. The eye was accidental, but the blood being poor could not restore it, and so it sloughed out. The scum on the other eye is due to the poverty of blood; also the sore on the hind leg. If the filly is worth treating from an economic point of view, it would be well to give her a teaspoonful of sulphate of quinine twice a day for a fortnight, then follow this with 15 drops of tincture arsenicum three times a day for a fortnight, then a tablespoonful of syrup of phosphate of iron twice a day for a fortnight. The first will be taken in food; the last two are better just placed on the tongue, but can be mixed with food if she is difficult to handle. The last being sweet, she will probably look for it. Boracic acid to the injured eye twice a week; nothing to the other.

"W. G. T." asks treatment for cow suffering from proud flesh in wound in hoof, sustained through treading on rusty nail.

Reply—Throw or otherwise control the cow and burn off the proud flesh with red-hot iron, then dress with a mixture of equal parts alum, bluestone, and Venice turpentine, put on a rag and kept in place by the boot. Renew the dressing daily for three days, then twice a week till well.

"M. A. C." asks treatment for cow with overgrown toes. She is very lame.

Reply—One of the symptoms of so called dry bible. Cut the toes with a chisel and mallet while the foot is on a block. Dress the hoofs once or twice a week with a mixture of equal parts mutton fat and Stockholm tar melted together. Give the cow twice daily in feed for a fortnight a mixture of 4 oz. bone meal,  $\frac{1}{2}$  oz. saltpetre, and 1 oz. syrup of phosphate of iron. Home measures—Small cocoa tin, dessertspoon, two tablespoons.

"W. K." asks whether it is cheaper to feed horses with peas at 28s. per hundredweight than to give them bran, and also whether it is advisable to add a little linseed meal to chaff.

Reply—Peas, even at 28s. per hundredweight, would be a cheaper feed than bran at present price; but from a practical point of view both are prohibitive at the money. Linseed meal in small quantities, about  $\frac{1}{4}$  lb. per feed once or twice a day, is helpful in such times as the present, and economical, as it acts as a mechanical laxative and keeps the bowels free from accumulations likely to occur on present dry feed.

"R. J. J." has pony which was given a bag of rubbish sweepings, grain and chaff. Two days later she was very lame, and could hardly walk; then developed strangles and broke out under jaw; the feet are now the trouble. He seeks advice.

Reply—Metastatic laminitis, otherwise founder, arising from digestive upset when strangles was in the system. Keep the feet moist and soft either by poultices, cowdung and tar, or wet clay; give 10 drops tincture of aconite three times a day, and 1oz. Epsom salts in drinking water morning and evening. Exercise.

"W. H.," Blyth, has calf, 7 weeks, which has gone blind, though eyes look quite natural. He asks if any cure.

Reply—Blindness, although the eyes seem quite natural, is called amaurosis, and is frequent in cows such as you describe, generally arising from a blood clot on the brain. Little can be done, but sometimes relief follows the use of 15 drops tincture belladonna given on the tongue morning and evening for a month or so.

"M. L.," Hornsdale, asks recipe for drench for water troubles in horses; also if Fowler's solution would do harm if given when worms are not present.

Reply—One-quarter to half a pint of gin, 25 drops of essence of peppermint, and half a pint of warm water form a very good drench for water troubles. A tablespoonful of mixed mustard on the tongue is also a good emergency remedy. Fowler's solution of arsenic runs 20 doses to the pint, and can be procured from any chemist, who will prepare a somewhat cheaper veterinary form if asked to. A course will do no harm even if worms are not present, which is extremely unlikely. Linseed oil, raw, is good if due care is taken in drenching not to force it down. This applies to any drench.

"C. A. H." seeks information as to food value for horses of potatoes, copra cake, and millet chaff, how they should be fed, &c.

Reply—Potatoes are fed to horses in some parts of the world, but when fed raw are likely to produce scouring, colic, and other digestive troubles. In Great Britain they are dessicated and used as a component of fancy foods; but they are only suitable for heavy horses at slow work, and given boiled or steamed. Horses should be brought on to them gradually till 20lbs. a

day may be given. If a start is made on this quantity the horses will probably die; 2lbs. to 4lbs. would do at first. The annexed analyses compare them with carrots, one of the finest horse feeds going :—

|                     | Potatoes. | Carrots. |
|---------------------|-----------|----------|
| Water .....         | 74.61 ..  | 84.37    |
| Albuminoids .....   | 2.17 ..   | 1.28     |
| Fat .....           | 0.15 ..   | 0.24     |
| Carbohydrates ..... | 21.23 ..  | 11.38    |
| Fibre .....         | 0.73 ..   | 1.62     |

The steamed skins are better rubbed off at first, gradually bringing the horses on to them.

A horse cannot be fed on copra cake alone. His digestion would give out, and he would die of starvation in spite of the high nitrogenous ratio, which is about 1 : 1.6. A maximum of 1lb. a day is as much as a horse can make use of, and this should be mixed with other food and divided into three feeds at least to get best value out of it. It is undoubtedly a valuable adjunct to other foods, but for the horse linseed cake, which is cheaper, is also better. The quantity used is the same. The horse does not require a large amount of fat in his food; ordinarily oats or maize supply his requirements. Just now maize is a reasonable food.

Millet chaff in many parts of India is the only feed horses get, and they work well on it. Its feeding value depends, like all hays, on the time it is cut and how it is cured. As the heads are chaffed, the analysis works out well : Water, 12.40; albuminoids, 10.14; fats, 2.20; carbohydrates, 73.37; salts, 1.35. Nearly half the value of lucerne hay. It should not be cut too fine,  $\frac{1}{4}$  in. to 1 in. lengths are readily eaten by horses, and as soon as they have been brought on to it, gradually at first, they pick up in condition. If inclined to colic at first, a little coke or salt counteracts the effect. Up to 30lbs. a day with a little hay may be fed to advantage, and in South Australia a much greater use could profitably be made of millet chaff. Ten years' experience of it has proved its value for all classes of stock.

#### WHEAT WEEVIL.

A correspondent inquires the best way of getting rid of weevil in wheat stored in a barn. The following, taken from a leaflet issued by the British Board of Agriculture, supplies the required information :—

*Life History and Habits.*—The females lay one egg in each grain. The grub, on hatching, feeds on the contents of the grain, and when full fed pupates in the eaten-out grain. In conditions extremely favorable to the weevils the whole life cycle can be completed in a month, but at lower temperature and under ordinary conditions a considerably longer time is taken. It has been shown that a temperature of 80° Fahrenheit is the most favorable for the development of the beetles. Moisture in the form of water vapor is very

favorable for the weevils. A close and confined atmosphere is also likely to favor the growth of these pests. The weevil lives for a long time. Kept in small corked tubes containing grain, in a sitting-room that had a fire in winter, some of these beetles (*C. granaria*) lived for nearly 14 months. On being touched or shaken the weevils feign death; they lie, often for a considerable time, refusing to show any signs of life, even when handled. They may be induced to move by breathing on them.

*Remedial Measures.*—1. Fumigation with bisulphide of carbon is a very satisfactory way of ridding grain of the insects. The grain to be treated should be put in a bin or airtight receptacle, and the bisulphide of carbon poured into a saucer or shallow vessel and laid on the top of the grain. The liquid volatilises, and the fumes, being heavier than the air, sink down through the grain and kill all insect life. One pound of bisulphide of carbon is sufficient for 100 bush. of grain. The airtight receptacle should be kept closed for 24 to 48 hours. A shorter time would do for small quantities of grain. In treating a store or mill, 1 lb. of bisulphide of carbon is sufficient for 1,000 cub. ft. of space. Before entering the mill after such fumigation the doors and windows must be thrown open for an hour or two in order that the place may be well ventilated. If necessary, a second fumigation may follow the first. Bisulphide of carbon has a very disagreeable odor, and as the fumes are poisonous, they should not be breathed, though a little will do no harm. *It is also explosive, and must be handled with care. No naked light should be brought near it, nor should the operator smoke.*

2. Infested grain may be run through a sieve or screen, the network of which is sufficiently fine to keep the grain back and yet let the weevils fall through; these being caught in a receptacle placed underneath containing paraffin. This sieving or screening, however, fails to reach grains containing eggs or developing larvæ. The same objection can be urged against the practice of screening under a strong air blast, for infested grain will still to some extent remain behind.

### HORTICULTURE.

A member of the Lyndoch Branch of the Agricultural Bureau asks the best way to prune vines that have suffered severely through the drought, and have made a few inches of growth only.

Mr. G. Quinn (Horticultural Instructor) replies—If the short shoot is ripened in the region of the lowest buds only, I advise cutting back to one bud. If the shoot is not ripened around the lowest bud upon it, cut it right off and trust to a base bud sending up a shoot. If the number of spurs on the vine is large, reduce them and cut those retained to one or two buds as the strength indicates. Vines usually rod pruned will probably need to be short spur pruned to enable them to recover and make good fruiting rods for the next season. This means little or no crop the next summer, unfortunately; but I see no alternative.

## AGRICULTURE.

Referring to the inquiry by "Pat," the following tables indicate the grain and whole produce returns from wheat crops grown at Roseworthy College on pea stubbles and bare fallows for the period 1906-1914 :—

| Year. | GRAIN PER ACRE. |                              |       |                                |      |       | TOTAL PRODUCE PER ACRE.    |       |                              |      |  |  |
|-------|-----------------|------------------------------|-------|--------------------------------|------|-------|----------------------------|-------|------------------------------|------|--|--|
|       | Plot.           | After<br>Peas.<br>bush. lbs. | Plot. | After<br>Fallow.<br>bush. lbs. | Bare | Plot. | After<br>Peas.<br>T. C. L. | Plot. | After<br>Fallow.<br>T. C. L. | Bare |  |  |
|       |                 |                              |       |                                |      |       |                            |       |                              |      |  |  |
|       |                 |                              |       |                                |      |       |                            |       |                              |      |  |  |
| 1906  | 4               | 19 27                        | 10    | 23 43                          |      | 4     | 2 8 58                     | 10    | 2 8 100                      |      |  |  |

Referring to the grain yields, it will be observed that the average return for the nine years period is 4bush. 2lbs. higher after bare fallow than after pea stubble. In seven out of the nine seasons the bare fallow crop has proved superior, and yet when we turn to the figures for whole produce, the pea stubbles are seen to yield higher results than the fallows. Taking the mean figures for the six years (1906-1911), the difference is 4cwts. 86lbs. in favor of the pea stubbles.

## IMPORTS AND EXPORTS OF PLANTS, FRUITS, ETC.

During the month of February, 1915, 6,311bush. fresh fruits, 6,402bush. of bananas, 11,467 bags of potatoes, 873 bags of onions, 114 packages of vegetables, and 10 packages of plants, trees, and bulbs, were examined and admitted at Adelaide and Port Adelaide under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910; 390bush. of bananas (over ripe) were destroyed. Under the Federal Commerce Act 465 cases of fresh fruits, 200 packages of dried fruits, 13 preserved, and 10 packages of seeds were exported to overseas markets during the same period. These were distributed as follows :—For New Zealand, 105 cases of grapes and 10 packages of seeds. For India, four packages of preserved fruit and 360 cases grapes. For London, nine packages of preserved fruit, 200 packages dried fruit, and 282 packages of honey. Under the Federal Quarantine Act 3,483 packages plants, bulbs, seeds, &c., were examined and admitted from oversea markets.

## ROSEWORTHY AGRICULTURAL COLLEGE.

### HARVEST REPORT, 1914.

By W. J. COLEBATCH, B.Sc. (Agric.), M.R.C.V.S., Principal Roseworthy Agricultural College.

(Continued from page 636.)

#### THE WHEAT CROP.

The total area of wheat harvested for grain in 1914 comprised 148·686 acres. The area grown under experimental conditions was 81·69 acres, and the balance—66·996 acres—formed portion of the general farm crops. The farm wheat area was made up of 33·022 acres in Ebsary's C and 33·974 acres in Nottle's B. The total yield from these two fields was 887bush. 13lbs., which corresponds to a yield per acre of 13bush. 15lbs. Included in the experimental wheat area were the Permanent Experiment Field, the Depth of Ploughing Plots, Grainger's Superphosphate Plots, and several blocks of one acre and over occurring amongst the seed plots in Nottle's A and Field No. 6B.

The following table summarises the year's results :—

TABLE IX.—*Summary of Wheat Returns for the Year 1914.*

|                          | Area,<br>Acres. |    | Total Yield,<br>Bush. lbs. |    | Yield<br>per Acre,<br>Bush. lbs. |

| Experimental crops ..... | 81·690          | .. | 818 34                     | .. | 10 1                             |
| Total .....              | 148·686         | .. | 1,705 47                   | .. | 11 28                            |

#### EBSARY'S C.

This consists of light mallee land with a sandy ridge in the south-east corner.

Past history—1899, bare fallow ; 1900, wheat ; 1901, bare fallow ; 1902, wheat ; 1903, bare fallow ; 1904, barley ; 1905, pasture ; 1906, bare fallow ; 1907, wheat ; 1908, rape ; 1909, bare fallow ; 1910, wheat ; 1911, barley ; 1912, pasture ; 1913, bare fallow ; 1914, wheat.

This field has been resting since 1911 and was, therefore, in good cropping condition. The fallow was twice cultivated in the early autumn and again just in front of the drill. The seed was sown in a moist seedbed with 2cwts. of standard superphosphate per acre between the 11th and 15th of May. Germination was even and vigorous and the young crop made satisfactory progress up to July. Towards the end of that month it began to show signs of distress, particularly on the side under College Eclipse. Later on, however, it appeared to recover, and since there was insufficient rain in the spring to account for this, it can only be attributed to the fact that this particular field benefited by an unusually heavy downpour at the end of April. In the tabulated results given below, the most remarkable figures are those recording the yields of Gluyas, and especially of selection 6 of that variety. Taking the three selections together, Gluyas has returned an average of 16bush. 49lbs. per acre over an area of nearly 20 acres, and with a top yield of almost nine bags per acre. No more striking testimony to the suitability of this variety for grain production in dry seasons could be required. A yield of over five and a half bags of plump marketable grain from relatively light land under a fall of 6.12in. of useful rains should arrest the attention of those who are cropping the light mallee lands on or about the margin of cultivation in this State.

The other variety, College Eclipse, was grown along a fence line fringed with trees and native shrubs, and the yield was observed to rise as the distance from the boundary increased. This variety, however, never made any spring growth, and, as a matter of fact, it was only allowed to stand for grain because it was not considered worth harvesting for hay.

TABLE X.—*Showing Details of Seeding and Yields of Wheats Grown in Ebsary's C.*

| Variety.               | Selection. | Area.<br>Acres. | Seed<br>per<br>lbs. | Date<br>of<br>Seeding. | Total Yield.<br>Bush, lbs. | Acre Yield.<br>Bush, lbs. |

#### NOTTLE'S B.

The earlier history of this field has been outlined already in connection with the hay harvest. Only five out of the 29 plots sown to wheat were selected for the grain harvest. Three of these plots consisted of King's Red, which was a long way the best of the early wheats in the field, and the other two, which carried Late Gluyas and Queen Fan varieties, were chosen to suit next season's scheme of cropping. As has already been intimated, the

have been exceedingly light, and with depleted stores of subsoil moisture the benefits accruing from deep tillage would not become apparent. At the end of 10 years it may be possible to view the mean results with an amount of confidence warranting the application of the deductions to the general practice of the farm. However, whilst it would be injudicious at this stage to modify our methods in accordance with the foregoing results, it is interesting to note the facts that appear to be borne out and that at present seem likely to become established. In the first place it is clear that the deep ploughing in the 1910 and 1911 fallows did not show up disadvantageously in the 1911 and 1912 harvests comparatively with the shallower working. The 1910 fallows received good soaking rains, the rainfall for that year being 23·87in., whilst in 1911 only 13·69in. were registered. Hence the opportunity arose for studying the effect of bringing to the surface the so-called sour subsoil in both wet and dry years. A glance at the table will show that the 8in., 10in., and 12in. plots compared very favorably with the shallower depths under both conditions. In total produce they were within the recognised margin of experimental error in every instance but one, and in the season preceded by heavy rains they gave consistently higher returns. Turning to the grain yield figures we find the position very similar, the experimental error being sufficient to account for the discrepancies in the two cases in which the shallow ploughing gave the higher return. These results come as a surprise, since they confront us with practical proof that so far as the heavier classes of loam in this district are concerned the subsoil to a depth of 12in. is not sufficiently crude and sour to injure the physical state of the land and ruin its fertility. The second point that appears to be clearly demonstrated is that 2in. fallowing is not going to prove as economic to wheatgrowers as 4in. The difference in yield amounts to approximately 2bush., which, at normal values, is equivalent to 6s. 6d. or 7s. per acre—an amount that would much more than cover the extra cost of ploughing.

The mean figures for the plots fallowed 4in. and over are virtually equal, and all that can be said at the present stage is that the arguments in favor of continuous deep fallowing in preparation for wheat have not been supported by the results. It is feasible to suppose that in the light of future results this conclusion may have to be revised.

With regard to the 1914 crop which extended over a total area of six acres, it may be said that seeding took place under almost ideal conditions. King's White (selection 6) was drilled in at the rate of 90lbs. per acre on the 25th of May, and the whole area received a dressing of 2cwts. of 36/38 superphosphate per acre. All the plots ripened off at about the same time, and they all lost a good deal of grain through the ravages of birds. The crop was cut about the middle of October and threshed a month later. The average yield over six acres was 9bush. 47lbs.

## GRAINGER'S SUPERPHOSPHATE PLOTS.

TABLE XIII.—*Showing 1914 Yields of Grainger's Superphosphate Plots, together with the Mean Yields, 1910-1914.*

| Superphosphate per Acre. | Total Produce per Acre. |    |    |                      |    |     | Grain per Acre. |                      |

(No grain harvested in 1911; plots cut for hay.)

There are five series of three plots in this experiment. Each series represents a three-course rotation, viz., bare fallow, wheat, and pasture, and the cereal crop is either not manured at all or else dressed with varying amounts of first grade superphosphate according to the preceding tabulated scheme. Each plot is 2.82 acres in extent and is securely fenced off to enable the stock-carrying capacity of the pastures to be determined and compared. In order to provide a good sole of "grass" for the accumulated surplus of manure to act upon and thus reveal itself by stimulating and maintaining a vigorous growth of feed, lucerne and rape have been sown in some seasons, but the former has become so expensive to purchase that its use for temporary pasture amounts almost to extravagance.

King's White (selection 6) was sown at the rate of 85lbs. per acre between the 12th and 14th of May. The unmanured plot made slow progress throughout, and although it yielded fairly well as compared with the mean grain return, it reduced the average yield of total produce by nearly 25 per cent. Allowing the usual 10 per cent. margin to cover errors traceable to factors beyond control, the average grain yields for the period 1910-1914 in respect of all the manured plots may be considered to be equal.

Turning now to the total produce, it will be observed that the results this season have been somewhat uneven. The returns from the  $\frac{1}{2}$ cwt. and the 2cwt. plots were approximately equal, whilst from the 1cwt. and 3cwt. plots the yields were 5cwts. to 6cwts. per acre less. According to the table of means the average yields of total produce over the past five seasons have been consistently increased by additional quantities of superphosphate. The influence of the accumulated manurial residues on the stock-carrying capacity of the land is discussed in separate reports.

## PERMANENT EXPERIMENT FIELD.

Biennial reports are issued in connection with the important work carried out in this field. It is sufficient to state here that the whole area harvested for grain was 52.224 acres, and that the average yield per acre was 10bush.

26lbs. This yield would have been considerably higher had there been other crops nearby to attract the birds. The variety of wheat grown was King's White (selection 6), which was drilled in at the rate of  $1\frac{1}{2}$  bush. per acre.

#### MISCELLANEOUS PLOTS.

In fields Nos. 6B, 5A, and Nottle's A, a number of seed plots were grown. They varied in size from two or three rows up to 3.386 acres, but, as previously mentioned, only those occupying an acre or over have been included in the average yield records. The treatment accorded these three fields prior to and during 1914 has already been referred to, and it now remains to group the results as under:—

TABLE XIV.—*Showing the Details of Seeding and Yields from Plots of One Acre or over grown in Field No. 6B and Nottle's A.*

## CHARACTER OF THE GRAIN.

Whilst it must be admitted that the later varieties, which were for the most part too ill-grown to be bound and threshed, yielded a small and somewhat shrivelled grain, yet the earlier and better grown varieties yielded a fine large plump and weighty sample, which graded up to approximately 66lbs. per bushel with an average loss of only 5.89 per cent. The following table summarises the grading operations for the year.

TABLE XVIII.—*Showing Percentage of Losses in Grading, and Bushel Weights of Wheats Harvested in 1914.*

| Queen Fan .....          | 4               | 43                 | 17   | 37               | 50   | 12.59 | 61                         | 62                        |
| Late Gluyas .....        | 6               | 25                 | 14   | 21               | 33   | 15.25 | 61½                        | 63                        |
| Totals for stripped area |                 | 210                | 49   | 174              | 19   | 17.31 |                            |                           |
| Combined totals .....    |                 | 1,497              | 15   | 1,384            | 57   | 7.50  |                            |                           |

Thus there is seen to be a very marked difference between the bushel weights of the threshed and the stripped samples. Despite the heavy grading of the latter, the bushel weight did not rise appreciably above the f.a.q. standard, which clearly indicates the poorly developed character of the grain. An extreme case is seen in the fourth selection of College Eclipse, which showed an increase of only half a pound a bushel after 28.2 per cent. of tailings had been removed. The best thresher sample was King's Red, but the percentage of loss on grading in both King's Red and King's White was, on the average, slightly higher than in Gluyas. The figure 7.71 in connection with Gluyas (selection 6) is comparatively high, but this is attributable to the series of stoppages that characterised our initial efforts to get the new Leviathan thresher mill into working order.

It would appear at first sight to be difficult to account for the difference between the 1913 and 1914 wheat samples, but on reflection it will be recalled that during September we experienced a number of frosts, some of which coincided with the flowering period, and it is probable that the effect of these, and the extreme heat during the early part of October, was to reduce the number of developing ovules per head, and thus indirectly to encourage the production of well-filled grains. In this connection, also, it is necessary to reiterate the statement that only the most promising blocks on the wheat area were reserved for grain.

#### GENERAL FARM AVERAGE.

Having regard to the nature of the season, and to the relatively low yields that have been obtained elsewhere on land of similar or even better quality,

the general average yield of wheat on the College Farm for 1914 must be regarded as very satisfactory. However, whilst a certain amount of credit may be fairly claimed for the system of farming and the thoroughness of the work which permitted such results to be obtained, there is no desire to obscure the fact that the figures quoted represent the average return from an area deliberately selected with a view to supplying our seed requirements for next season without encroaching on the available hay area any further than was absolutely necessary. In other words the exigencies of the season compelled us to bind or mow the poorest blocks for hay.

It has been the practice hitherto to include the experimental wheat area in the general farm averages, and the precedent has been followed again this year. In the course of the report, however, a distinction has been drawn between the ordinary farm crops and the wheat grown on the experimental areas, and in subsequent years it is intended to carry this distinction into the tables of yields. I quite recognise that on a seed wheat farm, where the varieties grown are of necessity much more numerous than is usual or advisable under a general farming system in this district, it is at times a difficult matter to say exactly where the line should be drawn between experimental and ordinary farm crops. It seems to me, however, that a useful purpose will be served by grouping all blocks that have not received special treatment as regards tillage or manuring, and that are not situated in fields reserved for systematic experimentation, under the title "Farm Crops," and keeping the records of the same distinct from those secured from experimental areas.

We can now look back over a period of 11 years during which reliable data concerning the wheat yield have been gathered and recorded, and it is with satisfaction that we find ourselves in a position to state that the average annual return per acre for the period 1904 to 1914 is within 6lbs. of 17bush. The actual details are here given :—

## SPEECH DAY AT ROSEWORTHY.

### ANNUAL DISTRIBUTION OF PRIZES.

The annual Speech Day and distribution of prizes at Roseworthy College on Friday, March 12th, was attended by a number of parents of students and visitors. The Minister of Agriculture (Hon. T. Pascoe, M.L.C.), presided, and others present included the Hon. W. Hannaford, M.L.C., the Director of Agriculture (Professor Perkins), and Messrs. F. Coleman, A. M. Dawkins, C. J. Tuckwell, and G. Jeffery (Advisory Board of Agriculture).

### THE PRINCIPAL'S REPORT.

The Principal of the College (Mr. W. J. Colebatch, B.Sc. (Agric.), M.R.C.V.S.), in his annual report, said—"The present occasion marks the termination of the thirty-first scholastic year in the history of the Roseworthy College. The total number of students enrolled since the inception of the institution is 610, and at the conclusion of to-day's function 228 diplomas will have been awarded. The percentage of diploma winners is thus seen to be 37.37 of the total enrolment, and if we include in our calculation only those who actually competed for a diploma, the percentage would probably range between 50 and 60.

"Consideration of these figures naturally leads us to inquire how high this percentage may be raised with advantage to the College and its alumni. At a glance it would appear that the success of its students furnishes a measure of the efficiency of a college as an educational institution, and that a high percentage of diploma winners must necessarily indicate ability and industry on the part of both staff and students. There are, however, other aspects of this question to consider. It will be readily conceded that a diploma which is disregarded by the general public, and, in particular, by that section of the community directly interested in the subject or subjects for which the diploma is granted, can have little value outside of the precincts of the institution concerned. It therefore behoves those in authority to see to it that the standard of scholarship demanded is such that only those who may confidently be expected to bring credit to themselves and their Alma Mater shall be stamped with the college hall mark of proficiency. In other words, our aim should be, and is, to make the college diplomas something more than a mere certificate that a certain degree of efficiency has been attained under a definite curriculum. The

more difficult of acquirement the diploma is made within reasonable limits, the higher will it stand in public estimation, and the more it will be coveted and valued by our students. On the other hand, if the diploma be cheapened by lowering the standard, the effect will, in the end, be disastrous to all concerned.

“We may count ourselves most fortunate at Roseworthy College that the framing of the system of education here in vogue fell into the hands of such well-trained and able men as Professors Lowrie and Perkins. They have been careful to shape the course so as to enable the institution to educate young men in the art, as well as the science, of farming. In this manner they have succeeded in preserving a proper balance between theory and practice throughout the course. To my mind, this has always been an outstanding feature of the Roseworthy curriculum, and I am inclined to attribute to it a very large measure of the success which our students have achieved in their extra-collegiate careers. For, be it remembered, the Roseworthy College graduates have made a name for themselves in all branches of rural industry as well as in other walks of life. There is thus ample evidence that the efforts made to found a course of study and establish a diploma standard that will fit the conditions and requirements of our State have not been futile. On the contrary, a goodly measure of success may fairly be claimed, and, I am sure, will be readily allowed.

“We do not anticipate for a moment being able to satisfy the demands of all our candid friends. There are always some misguided and narrow-visaged individuals who find serious difficulty in understanding why all students who gain the diploma do not exactly conform to their own particular notions as to what a college graduate should be. They fail to recognise that we do not, in general, endeavor to train men in any one particular branch of agriculture, but rather to turn out a steady stream of young fellows possessed of a good all-round knowledge of the rural sciences, and with an adequate training in farm operations. We fully realise that at the time of their graduation from the college they are not all equally adapted for each and every phase of agricultural work. Some will prefer one pursuit and others another, and it would be unreasonable to suppose that mistakes will not occur in the choice of avocation, even amongst Roseworthy diploma holders. Those who already have entered upon manhood prior to leaving the College have, as a rule, settled upon definite plans for the future, and such men are usually capable of making an immediate start in the business of farming. On the other hand, some of our most intellectual graduates secure the diploma at about 19 years of age, and, whilst exceptional instances occur, it would be injudicious as a general practice to load these youths with the full responsibilities of farm man-

agement until they have gained additional experience. It is not a function of this College to place old heads on young shoulders, nor can we be expected to turn out youths, still in their teens, fully equipped with powers of judgment and discernment that can only be attained by years of experience in the stern school of life.

“At a residential college, the members of the instructional staff have an opportunity of becoming intimately acquainted with the character, abilities, and diligence of their students, and it may reasonably be urged that they are, *ipso facto*, better fitted to conduct examinations in their respective subjects than others unfamiliar with the mental endowments and personalities of the competitors. The relative merits of the two systems of examination have been frequently discussed. It is contended, on the one hand, that men who have been closely associated with the candidates must, consciously or unconsciously, lean towards those who have worked consistently and well during the course, but have met misfortune in the examination, and, further, that the appointment of extra-mural examiners will eliminate this disturbing influence. As against this view, it may be pointed out that experience has shown that the introduction of the extra-mural system, without restriction, would occasionally lead to great hardships, and, at times, to scant justice. In order, therefore, to uphold the standard of the diplomas, and at the same time to protect the interests of our students, the Roseworthy practice has been to appoint outside men to act in conjunction with our own staff, and thus secure to us the advantage of both systems. I take this opportunity of thanking those gentlemen who have so kindly assisted us as co-examiners.

“Before leaving the subject of the college diploma, I would like to lay some emphasis on the fact that whilst it should be the ambition of every student to win the coveted piece of parchment, yet, in the end, it is the attainment of education and not the acquisition of awards that should constitute the objective. It is not every good student that is fortunate enough to earn a diploma, and I would say to those who have been unsuccessful on this occasion, that we number amongst those of whom the college is most proud, many students who were unable to qualify for a diploma.

“We will now pass briefly in review the chief incidents that occurred at the College during the past year. In some respects it has been one of the most eventful periods in the annals of the institution. Important changes have transpired in connection with the personnel of the staff. The advancement of Professor Perkins, which has met with such unanimous approval throughout the State, led to a change in the principalship, and the well-merited promotion of Mr. Spafford left

a serious gap in our ranks which another old student, Mr. Scott, is zealously endeavoring to fill. Alterations in the administrative staff during the course of a College year are usually to be deplored, and although in this instance the changes were effected as smoothly as possible, it would be fatuous to suppose that they did not involve some sacrifice. However, it is to be hoped that our efforts to mitigate the attendant disadvantages have not been made in vain.

“The season, as every one is well aware, has broken all previous records. Not one single bag of grain has been sold off the farm this harvest. The irony of it all lies in the fact that the new Leviathan threshing mill, which was available to us for the first time this year, is capable of handling 1,000bush. per day, whilst our total production of threshable crop amounted to less than 1,500bush. I will not, however, dwell on this rather hackneyed subject; suffice it to say that the Sahara-like conditions have tried the patience almost beyond endurance, and unfortunately, have to some extent affected the training in practical work.

“There is yet another event that has influenced us all in the discharge of our various duties, and it is one that transcends all others in importance. I refer to the great war in which our Empire and its Allies are engaged, and which has obsessed the minds of the whole British nation. It does not detract from the merits of either the staff or students to admit freely that both have experienced unparalleled difficulty in concentrating their thoughts and attention upon the subjects of the curriculum during so critical a period of the nation's history. It is very natural and proper that the outbreak of hostilities should have created a feeling of unrest amongst the young men of this College, and we are all proud to know that, at the present moment a member of our staff, Mr. S. H. Best, and two class mates of our senior year, Basil Fuller and Sydney Hayter Reed, are in the fighting line. In addition, a large number of old students have responded to the call to arms, and, with your permission, we will pay each and all of them the honor of special mention in this year's address. The roll of honor, which has been alphabetically arranged, is as follows:—S. H. Best, W. B. Blue, E. O. Brown, D. J. Byard, B. Fuller, D. Fulton, C. E. Goddard, K. T. Hamilton, B. Hocking, J. Hocking, R. C. Jacob, E. R. James, E. W. Jones, E. M. Judell, W. M. Kay, D. H. Killicoat, P. D. Killicoat, H. W. Leake, R. H. F. Macdinoe, J. S. Malpas, G. G. Masson, W. J. Naish, S. H. Reed, A. C. Sandland, H. E. Sibley, A. C. Smith, H. Stephen, J. A. B. Stevenson. M. G. Stewart, P. A. Tod, F. J. Treloar, S. C. Vohr, G. R. Webb, G. E. Wells.

"Prominent amongst the old scholars who have distinguished themselves in other fields are the Hon. H. A. Parsons, LL.B. (Attorney-General and Minister of Education), and Mr. T. E. Yelland (silver medallist, 1891), who has been elected to the Mayoralty of the City of Unley. Mr. F. K. Watson, who was gold medallist in 1908, has graduated in engineering, and will shortly complete the course in agricultural science at the University of Edinburgh. Mr. C. F. Stephens, Ridley scholar and gold medallist in 1913, who is studying for the B.Sc. degree in agriculture at the Adelaide University, has secured a first-class in mathematics, chemistry, physics, and botany, and has also passed in physiography. To each and all of these, we offer our most cordial congratulations.

"It now remains for us to do honor to those who have won a place on the list of this year's awards. The most important prize of the year, namely, the Ridley Scholarship, falls to the dux of the College, Oscar Sturt Symon, with 87.6 per cent. of the available total. He thus gains a first-class diploma, as also does F. H. Dealy, with 82.1 per cent., and the diploma average for the class works out at 68.89 per cent. Eleven out of the 14 competitors are entitled to receive diplomas, and we take pleasure in offering our senior class very hearty congratulations on the excellent results they have secured.

"In conclusion I would add a word of gratitude to those friends and well-wishers who have so kindly donated medals and prizes."

#### DIPLOMAS (IN ORDER OF MERIT).

##### *Diplomas of the First Class.*

Oscar Sturt Symon, with honors in Agriculture, Viticulture, Enology, Dairying, Veterinary Science, Chemistry, Bookkeeping, and Aviculture.

Francis Henry Dealy, with honors in Viticulture, Chemistry, and Bookkeeping.

##### *Diplomas of the Second Class.*

James Johnstone Graham, with honors in Bookkeeping and Aviculture.

Franz Oscar Henry Martin.

Reginald Lansell Frew.

Robert Angus Keddie, with honors in Aviculture.

Walter Anstruther Ross, with honors in Aviculture.

Henry Hubert Orchard, George Collard Walkem (equal).

Spencer, James Sibley.

George Charles Plowman Prevost.

#### PRIZE LIST.

##### *Third Year Students.*

Gold medal (presented by the Agricultural and Horticultural Society, for the highest aggregate in all diploma subjects), Oscar Sturt Symon.

College second prize, Francis Henry Dealy.

Old Students' Cup (presented by the Agricultural College Old Collegians' Association, for the highest aggregate in Agriculture and Veterinary Science), Oscar Sturt Symon.

Viticulture (prize presented by Mr. H. E. Laffer), Oscar Sturt Symon.

Fruit culture (prize presented by Mr. Geo. Quinn), Francis Henry Dealy.

Enology (prize presented by the S.A. Vinegrowers' Association), Oscar Sturt Symon.

Chemistry (prize presented by Mr. J. H. Phillips, B.Sc.), Francis Henry Dealy.  
 Veterinary science (prize presented by Mr. F. E. Place, B.V.Sc.), Oscar Sturt Symon.

Practical examinations (prize presented by the members of the Advisory Board of Agriculture), Oscar Sturt Symon.

Ploughing (prize presented by Professor Perkins, Director of Agriculture), Franz Oscar Henry Martin.

Outside work (prize presented by the Albert Molineux Memorial Trust), Henry Hubert Orchard.

*Second Year Students.*

Silver medal (presented by the Albert Molineux Memorial Trust), Thomas Sydney Dealy.

College second prize, Stuart Gawler King.

Agriculture and farm diaries (prize presented by the Principal), Stuart Gawler King.

Viticulture (prize presented by H. Buring, Esq.), Stuart Gawler King.

Fruit culture (prize presented by Mr. H. E. Laffer), Thomas Sydney Dealy.

Veterinary science (prize presented by the Principal), Thomas Sydney Dealy and Bryant Charles Hamilton (equal).

Practical examinations (prize presented by the members of the Advisory Board of Agriculture), Stuart Gawler King.

Outside work (prize presented by the Albert Molineux Memorial Trust), Bryant Charles Hamilton.

*First Year Students.*

Silver medal (presented by A. L. Brunkhorst, Esq.), Frank Riggs.

College second prize, Victor Thomas O'Grady.

Agriculture and farm diaries (prize presented by the Principal), Frank Riggs.

Bookkeeping (prize presented by Mr. H. C. Pritchard), Kenneth Clifford Catt.

Botany (prize presented by Mr. A. J. Adams, M.A.), Victor Thomas O'Grady.

English (prize presented by Mr. A. J. Adams, M.A.), William Hartley Lewcock.

Outside work (prize presented by the Albert Molineux Memorial Trust), Frank Riggs.

Speeches appreciative of the College were delivered by the Minister, Professor Perkins, and others, after which Mrs. Pascoe presented the diplomas and prizes to the successful students.

Haymaking

## GOVERNMENT INSPECTION OF STALLIONS.

## LIST OF CERTIFICATED HORSES.

The list up to December 31st, 1914, of stallions certificated for life, is as follows :—

| Name of Horse.           | Age.    | Owner.                   | Address.         | Date.    |
|--------------------------|---------|--------------------------|------------------|----------|
| <b>DRAUGHTS.</b>         |         |                          |                  |          |
| Abbots Fancy .....       | 5 years | H. W. Payne .....        | Rhine Villa...   | 7/7/13   |
| Acorn .....              | Aged    | J. Lehmann .....         | Pinnaroo .....   | 27/10/11 |
| Ballock Major .....      | 5 years | H. H. Hancock .....      | Quorn .....      | 27/8/13  |
| Banker .....             | 5 "     | J. A. Sudholz .....      | Kalangadoo ..    | 1/9/11   |
| Baron Grant .....        | 5 "     | W. T. Hall .....         | Jamestown ..     | 17/9/13  |
| Baron Idadale .....      | 5 "     | F. W. Doering .....      | Dutton .....     | 19/7/12  |
| Baron Newlyn .....       | 7 "     | M. Rasheed .....         | Redhill .....    | 7/7/14   |
| Bayonet .....            | 5 "     | E. Wright .....          | Meningie .....   | 23/9/13  |
| Belfast .....            | 5 "     | A. G. David .....        | Kadina .....     | 4/8/11   |
| *Belted Knight .....     | Aged    | A. Blum .....            | Lameroo .....    | 28/10/11 |
| *Bengall II. ....        | 5 years | A. Boutell .....         | Jamestown ..     | 29/7/11  |
| *Ben Lomond .....        | 7 "     | H. W. Steinwedel .....   | Balaklava ..     | 24/9/09  |
| Billy Ballance .....     | 5 "     | W. R. Lang .....         | Narridy.....     | 31/8/14  |
| Black Boy .....          | 5 "     | W. B. Pfitzner .....     | Robertstown ..   | 25/8/13  |
| *Black Knight .....      | 7 "     | I. Robertson .....       | Mannanarie ..    | 22/7/11  |
| Black Prince .....       | 5 "     | M. Daly .....            | Wilmington ..    | 27/8/13  |
| Blondin .....            | 7 "     | H. W. Sambell .....      | Yongala .....    | 2/10/11  |
| Bonnie Blue .....        | 5 "     | E. A. Hoffrichter .....  | Denial Bay ..    | 27/5/12  |
| Bonnie Kelvin .....      | 5 "     | Hill Bros. ....          | Georgetown ..    | 19/6/14  |
| *Bonnie Lad .....        | Aged    | J. A. Jaensch .....      | Murray Bridge    | 23/3/10  |
| Bonnie Laddie .....      | 5 years | Mark Coleman .....       | Anama .....      | 16/7/12  |
| Boro Primate .....       | 5 "     | Mark Coleman .....       | Hart Siding ..   | 26/7/12  |
| Botany .....             | 5 "     | E. G. Polgreen .....     | Cowell .....     | 2/8/12   |
| *Bramhope Monarch ..     | 6 "     | G. Weatherall .....      | Hahndorf .....   | 10/3/10  |
| Bright Star .....        | 5 "     | J. H. Dawkins .....      | Angle Vale ..    | 17/4/14  |
| Briton .....             | 5 "     | Sanders Bros. ....       | Hoyleton .....   | 2/8/11   |
| †Brown Boy .....         | 6 "     | M. C. Kennedy .....      | Millicent .....  | 27/10/09 |
| Brown Knight .....       | 5 "     | W. Schlink .....         | Hillsea, W.C.    | 18/6/14  |
| *Brutus .....            | 7 "     | John Head .....          | Lillimur, Vic.   | 24/8/12  |
| Camillus .....           | 6 "     | J. P. & L. Schinckel ..  | Mt. Gambier ..   | 20/10/09 |
| Campbell's Prince .....  | 5 "     | Findlater & Warren ..    | Milang .....     | 30/7/12  |
| Captain Jock .....       | 5 "     | W. J. Troubridge .....   | Lameroo .....    | 28/10/11 |
| *Carmyle .....           | Aged    | A. Worrall .....         | Saddleworth ..   | 9/8/10   |
| Carmyle Tweedside....    | 5 years | Geo. Keeley .....        | Streaky Bay..    | 20/6/14  |
| Champion .....           | 5 "     | A. R. Ramsay .....       | Cowell .....     | 17/5/12  |
| Chatsworth Warrior ..    | 5 "     | H. J. Growden .....      | Rocky River ..   | 1/8/13   |
| Clyde .....              | 8 "     | J. A. Walker .....       | Penola .....     | 13/10/09 |
| Clydesdale Ben .....     | 6 "     | G. A. Griffiths .....    | Carrow .....     | 29/8/10  |
| Clydesdale Willie....    | Aged    | J. P. Jackson .....      | Mt. Barker ..    | 8/3/11   |
| Codley's Forest Hero ..  | 5 years | Hill Bros. ....          | Georgetown ..    | 7/6/12   |
| Colac .....              | 8 "     | Ed. Goode .....          | Kingston.....    | 20/9/10  |
| Colleshill Jolly King .. | 5 "     | R. M. & H. C. Hawker.    | Bungaree .....   | 2/9/13   |

## THE HORSE.

### COMMON DISEASES OF THE DIGESTIVE ORGANS.

[By F. E. PLACE, B.V.Sc., M.R.C.V.S., Veterinary Lecturer.]

*(Continued from page 657.)*

The lips are at the beginning of the digestive tract, and it is not uncommon for horses to be put off their feed through slight injuries to them and to the lining of the cheeks. A horse eating hard dry food will sometimes run prickles and thorns into the lining of the lips and cheek. These form little abscesses not unlike gumboils in human beings. If a horse seems tender about the mouth it is just as well to look inside his lips and under his tongue, and if an abscess is found, it may be opened with the point of a sharp knife. Nature will do the healing; but, if the mouth and tongue are very sore they may be swabbed with a solution of Condyl's crystals, just pink, or a mixture of one part alum and seven parts boracic acid may be dusted on.

#### THE TEETH.

In youngsters we meet with teething troubles as with babies, but, as the nervous system of the horse is not nearly so sensitive as the human, he does not make so much fuss; nevertheless, he suffers a good deal of inconvenience. When this is the case a little cooling medicine of any description will ease the trouble. For instance, 1oz. of Epsom salts given in the drinking water or mixed with the feed twice a day for four or five days. In yearlings or 2-year-olds a small teaspoonful of saltpetre, or as much as will lie on a sixpence of grey powder (mercury and chalk), roughly, 30grs. or 40grs., will be a fair dose, given once a day for a week. The soreness of the gums will rapidly disappear under this treatment. Immediately behind the incisor teeth on the top jaw we find the trouble called "lampas." It is not a disease, it is simply a filling of the palate with fluid, and it is not painful, as may be shown by pressing on it with the thumb nail. However, the palate seems to be lower than it should be because the teeth are not so long as they will be. There is no doubt, while teething is going on, that the mouth is sore and tender; but this is in the gums, not in the lampas. The treatment would be a change of food—soft, such as bran for preference, and cooling medicine as above. However, if an operation is desired, take a shoeing nail or three-

pronged fork and prick the lampas in several places. Do not use a knife, because between the second and third bars the two arteries which supply the sides of the mouth unite, and if they are cut the bleeding will be profuse. Should such an accident occur, put a pad of rag against the roof of the mouth and tie it tightly round the nose with tape. A little alum, saltpetre, or salt may be rubbed in at the pricking the lampas, which will disappear as the teeth grow longer.

#### THE TONGUE.

The tongue is very often the seat of trouble arising from prickles, grass seeds, &c., which enter the tongue generally by the salivary ducts underneath it, and are buried so deeply that large and painful abscesses are set up and the tongue becomes a hard immovable mass. In such cases, examine the tongue well, lance any abscess that can be noticed, and apply the same treatment as for lampas. The tongue also suffers from abrasions caused by irregular teeth. These are not so common as is generally supposed, but are rather painful. Swabbing with Condy's crystals, the solution being port wine color, will effect a cure.

#### IRREGULAR TEETH.

The action of the molar teeth is to shear and to grind. There are times when the molar teeth interfere with the horse's digestion. Sometimes the hindmost do not meet their opposites correctly. They either grow down or grow up to such an extent that the jaw bone is pierced by the overgrowth of the teeth. To find out whether this or other trouble is going on, back the horse into a corner, get someone to steady his head, grasp the tongue with one hand, hold a handful of the tip of the tongue and turn the hand upwards. This will form a gag, and with the light shining over the shoulder, the whole surface of the molars can be seen. If anything is wrong, which is seldom the case, call in a qualified veterinary surgeon to attend to it. The fourth molar on the lower jaw will sometimes be overgrown. Skilled treatment is required for this trouble. Sometimes milk teeth are not shelled or cast properly, and remain as caps on the permanent teeth and so interfere with chewing. They may be prodded off with a piece of stick.

*Breaking or Decaying of Teeth.*—Occasionally a horse jams a piece of splinter down between his teeth, which causes considerable pain, and he shows it either by going at a mad pace or jibbing, or, if he is in the stable, by rubbing the side of his head on the manger. In such a case look for the trouble and remove it. As the nerve becomes more and more exposed it will be destroyed and the horse will be all right.

#### THE THROAT.

*Choking in the Gullet.*—A greedy feeding horse will sometimes swallow his chaff hurriedly, then back off from the manger, poke out his head, slobber at the mouth, and sometimes squeal. If one then looks at the near side of

the channel of the neck, a swelling will be noticed about half-way down caused by the wad of chaff sticking there. This obstruction will possibly give way to pressure ; if not, put a billet of wood underneath it and strike it fairly forcibly with a smooth round piece like a rolling pin, at the same time rubbing from above downwards. Do not drench with oil or water, but give about a teacupful of milk, which will ferment and break up the chaff. The horse, however, may draw his head into his chest and stand bunched up. In such a case the choke has occurred in the chest near the entrance to the stomach, quite out of reach ; but, as exercise causes the diaphragm to move quickly, brisk exercise will help to remove this trouble, and milk is also useful.

#### STOMACH TROUBLES.

When the horse suffers from stomach trouble he generally shows it by dulness of the eye and lopping ears. There may be a swelling under the belly, but not necessarily. The bowels will be irregular and, perhaps, the urine high colored. In such cases a purgative should be given—one of the best is raw linseed oil from one to two pints. Sometimes the horse sits up on his hindquarters like a dog. This points to trouble in the walls of the stomach, very often abscesses caused by worms which sometimes perforate the walls of the organ, in which case the horse vomits. When a horse is suffering in any part of his digestive tracts his favorite position will be lying down, not necessarily for any length of time ; perhaps lying still, perhaps rolling about ; and after he has eaten a little he becomes restless, throws himself down, lies on his side, brings his head round to his chest and probably bites at it. He is trying to tell us that the pain is behind the breastbone. If, when he is standing up, one prods him in this neighborhood, he will flinch and groan. The trouble, in the great majority of cases, will be impaction or overfilling of the stomach or some part of the large bowel. Oil, as a purgative, is the best thing to start with—raw linseed oil, from a pint to a quart, preferably given in two doses at two hour intervals. Olive oil may be used similarly, or mixed with half a pint of castor oil, in which case a little warm milk may also be added to prevent the oil sticking in the mouth. Stomach troubles, as a rule, do not appear to be acute ; the horse works fairly well, eats fairly well, but in this respect is irregular and, with the exception of dulness and occasional pain, he does not seem to have anything serious the matter with him. However, if he sits on his haunches and remains in that position for 10 or 15 minutes, he will show by his face that he is in very great pain. His nostrils will be drawn, his eyes sunken, and there will be a greenish discharge from his nostrils and, perhaps, from the mouth. This indicates that the walls of the stomach are badly injured. The muscle at the entrance which ordinarily prevents him from vomiting is unable to act and the food is forced up. In such cases a recovery is practically hopeless ; the horse does not respond to any treatment ; and large doses of medicine to kill pain

are required, such as 1oz. to 1½ozs. of chloral hydrate. After the stomach come the small bowels, where, however, trouble is not common. Only rarely does inflammation set in in them, and then it is generally of a mechanical nature. The small bowels are continually moving—peristalsis. They move and twist with a wormlike movement, and it is possible for them to overlap and so become tied, causing extreme pain. The horse does not throw himself down or roll about, but bends his knees and his hocks, and goes down gently, not right down, as a rule; sweats freely, and appears in great pain. When we find the horse with the symptoms just described and a thin, weak, fast pulse, we may suspect gut tie. Sometimes it is possible to remove this condition by dissolving an ounce of tartaric acid in a pint of warm water and giving as a drench, following in a few minutes with an ounce of baking soda similarly dissolved. A large quantity of gas will be formed in the stomach and, having no free escape forward, will have to work backward and so remove the interruption. If, however, the gut is firmly tied, this proceeding will kill the horse all the quicker. Poisons of various sorts cause acute inflammation in the small bowels. Weeds, like the *Euphorbium drummondii* with its bright green leaves and milky juice, is very attractive to young horses and kills them in this way. The lips and tongue are somewhat swollen and the mouth is a little sore. From 1½ pints to 2 pints of milk are useful in such cases, and in practically any form of poisoning except phosphorus.

#### DIGESTIVE TROUBLES IN THE LARGE BOWELS.

Nine-tenths of the digestive troubles of the horse occur in the large bowels and follow a change of food or method of watering or working, especially in horses which come into work after a spell. The horse will appear uneasy, break out into patchy sweats on the flanks, and not work as well as usual. When brought in he eats a few mouthfuls, begins to scrape with his front legs, looks round at his flanks, throws himself down and rolls. He does not pass his water as usual and, in the intervals between rolling, gets up and attempts to do so, so that the trouble is generally considered to be stoppage of the water. However, when the horse wants to pass water he stretches out his legs, draws in his belly muscles, and by the pressure passes it freely. Now, when there is acute pain in the large bowels, it is far easier to retain the urine in the bladder than to adopt this position; therefore, he does not pass his water till free from pain, and, as most medicines given cause a cessation of pain, the subsequent passing of water is looked on as a good sign. The main lines of treatment for stoppage of the water are to pass the greased hand into the hinder bowel and remove the dung that has accumulated. This emptying of the hind bowel will cause those further forward to pass their contents backward and so relieve the pain. The bladder may be felt under the hand and will generally be a fluctuating ball rather larger than a navel orange; but it may be larger than a football, in which case there is un-

doubtedly retention of the urine. If the bladder is squeezed gently the trouble may be got over. If not, the penis should be drawn and a small enamel funnel placed in the opening and about a pint of warm water poured in. This will cause the animal to pass his urine. In the case of the mare, if the bladder is overful, she will naturally relieve herself; or the greased hand will find on the floor of the vagina a flap guarding the opening of the urethra into which two fingers may be inserted and the urine will flow freely. Medicines, like sweet nitre and laudanum, which are often given with a view to acting on the kidneys and bladder, act as stimulants and painkillers on the bowels, causing more active movements in them and passage of the gases that have accumulated. A distention of the large bowel is caused by fermentation of their contents, so that recognising the condition by the distention of the flanks the pain can be relieved without the use of drugs. The flanks and the last two ribs should be rubbed vigorously with a little mustard or liniment if preferred, and half a teaspoonful of household ammonia may be given in a little cold water as a drench, or a tablespoonful of baking soda dissolved in warm water, or a knob of blue or a dessertspoonful of washing soda, or a tablespoonful of mixed mustard may be put upon the tongue. Strong coffee may be given with advantage, or if it is available, alcohol is preferable in any form, such as half a teacupful of methylated spirits. The best, however, is gin, on account of the small quantity of juniper contained in it, which acts both as stimulant and sedative on the bowels. A reliable colic drink consists of  $\frac{1}{4}$ pt. to  $\frac{1}{2}$ pt. of gin and a good nobbler of peppermint cordial, or 25 to 30 drops of essence of peppermint and  $\frac{1}{2}$ pt. of warm water. In very severe cases, 10 drops of tincture aconite may be added. Nux vomica, in small doses, is an excellent bowel stimulant, and ammonium causticum is the same as household ammonia. There is a great advantage, however, in giving the small homoeopathic doses, as they may be put into the mouth mixed with treacle, bran, pollard, &c., and so do away with the risk of drenching. However, when aconite is given it should be remembered that it is a very powerful drug and must not be repeated too frequently. Sometimes the above treatment may not give relief, and then there is probably an accumulation of undigested dung in the bowels, in which case the pain will not be so violent, the intervals between lying down will be longer, and the disease will last for some days. Rubbing the flanks and the bowels and giving exercise will be of use. Enemas will also help and not less than 4galls. should be given. A  $\frac{1}{2}$ lb. of soap should be shredded up and dissolved in very hot water; this should then be stirred into a kerosine can full of tepid water. The soap in the enema will both lubricate and stimulate the bowel. A few feet of hose pipe is better than a syringe. A couple of feet should be greased and passed into the bowel, a large funnel placed in the other end and held well above the horse, and the enema poured in. Administered in this way it will be retained long enough to thoroughly soften the bowel

contents. If, however, the desired effect is not obtained, mix 4ozs. of glycerine with the enema. This will cause the horse to strain and pass a large quantity of dung. If impaction is the cause of the trouble it will probably be in one of the bends of the fourfolded colon near the back of the breastbone towards the near side, or it may occur in the large water gut on the off side, in which case there will be a ridge along the side of the belly about 4in. below the ridge of the ribs. The impaction is generally due to undigested straw knots, binder twine, twigs, and such like material; occasionally hair is felted into balls or phosphatic salts from the food accumulated into larger stones known as calculi. The symptoms are attacks of gripe or colic at short periods, the pain being severe and lasting for some time, and it is only natural when such heavy masses accumulate in the bowels that a good deal of friction will arise which will cause the bowel to wear through, in which case, of course, there is no hope for the horse. In impaction cases a brisk purgative is advisable; give bran mash only for a couple of days and then a dose of aloes. For a draught horse 1oz. is recommended. Administer as a ball or dissolved in warm water, in which case add a tablespoonful of baking soda. Twelve to 24 hours after this is given the horse will scour freely and the accumulation in the bowels will be got rid of. There are other drugs which may be given with better effect, but they require special skill in handling. However, in obstinate cases two areca nuts may be ground up and mixed with sufficient water or milk will cause violent action. As in the case of the small bowels, the large bowels may be twisted or displaced. With a greased hand in the hinder gut, one of the bends of the large colon may be reached and the twist felt. Impaction of the bowels often continues for a fortnight or even longer, and, in addition to purgatives, stimulants will help. Soap is to be recommended; a ball of 2ozs. of soap put down the horse's throat once a day for two or three days will bring about satisfactory results, or it may be dissolved and given as a drench with 1oz. or 2ozs. glycerine added. Nux vomica is also useful; either a teaspoonful of powder once or twice a day in milk or feed, or the tincture 10 to 20 drops three times a day. Do not omit the rubbing. The symptoms of a burst in the bowel will be a weak rapid pulse, the skin harsh and dry, not a great amount of pain, probably constantly walking round and round.

#### PERITONITIS.

Inflammation of the lining of the belly, with small chance of recovery. Repeated stimulation outside and medicines to ease pain internally. One of the best ways of applying external heat is to put the skin of a freshly flayed sheep, skin side down over the horse's loins. Bleeding may be resorted to. One or two quarts of blood removed will give nature a chance of fighting with remedies of her own provided in new blood. To ease pain give laudanum in two to four tablespoonful doses,  $\frac{1}{2}$ pt. doses of chloroform water; veterinary chlorodyne, according to the dose on bottle or tin; or a large-sized bottle of

human chlorodyne; chloral hydrate, in 1oz. doses, has a marked effect in relieving pain—being a solid, if kept in a well-stoppered bottle, it will keep good almost indefinitely. It may be given to the horse as a ball, wrapped in paper, or with a pint of warm water as a drench, or injected as an enema. The dose may be repeated if necessary in two or three hours.

#### KIDNEYS AND BLADDER.

The horse's urine is often thick and dark colored, but the kidneys are not necessarily diseased. A heaped teaspoonful of saltpetre may be given two or three times a day. The liver is probably the seat of the trouble, and as the saltpetre stimulates the liver the trouble will be removed. When the horse is continually trying to pass water which dribbles away and is sometimes bloodstained, there is probably a collection of sandy matter in the bladder. This may be felt through the hinder bowel. In such cases do not give saltpetre, but teaspoonful doses of bicarbonate of potash and similar doses of camphor, or 10 to 20 drops of the tincture of camphor.

#### WORMS.

The long round worms lie in the small bowel and may be removed with linseed oil or aloes. Whip worms lie about 2ft. inside the hinder bowel, and an enema of a quart of warm milk with two tablespoonfuls of turpentine will drive them out. Blood worms, large and small, attach themselves to the lining of the bowels, and pierce through into the blood vessels, where they live and multiply. Give Fowler's solution of arsenic, two tablespoonfuls once a day for a fortnight; stop for a fortnight, and repeat for a fortnight. The worms may not be seen in the dung, but the general improvement in health will show that they are being killed. Bots do not cause very much trouble, as they cause no inflammation, though when very numerous, may mechanically interfere with the passage of food out of the stomach, where they stay for about eight months. To remove them starve the horse for 24 hours, mix half a teacupful of fresh ox gall with  $\frac{1}{2}$ pt. of warm milk and drench. Follow in an hour or so with a pint of raw linseed oil and a tablespoonful of turpentine. In this way the bots may be driven out. A red rag with flapping ends tied round the horse's neck, or tar and oil applied to the chin, will prevent the fly from laying her eggs on the long hair of the beard.

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, March 10th. The chair was occupied by Mr. F. Coleman, and the following members were also present:—Professor Perkins, Messrs. W. J. Colebatch, C. E. Birks, Geo. Jeffrey, C. J. Valentine, J. Miller, C. H. Tuckwell, A. M. Dawkins, and H. J. Finnis (Acting Secretary).

### CO-OPERATION AMONG THE PRODUCERS.

The Board indorsed the determination arrived at by the congress in September last that the two papers on "Co-operation" submitted at that gathering should be referred to the Branches for consideration, with the idea of the matter being further dealt with at the coming congress.

### CHAPMAN CORNSACKS.

It was decided to forward the following communication to the Minister of Agriculture, with a request that it be transmitted to the Minister of Customs:—"The attention of the Advisory Board of Agriculture has been directed to the difficulties raised at shipping ports by the Customs authorities in connection with the weight of the Australian standard (41in. by 23in.) cornsack when filled with wheat. The Board feels that producers are very awkwardly situated in that respect, and respectfully requests that you will bring the matter under the notice of the Federal Minister for Trade and Customs. The position, so far as the Board is concerned, may be summarised as follows:—The Chapman sack, which is now used throughout the Commonwealth, is the only recognised legal sack for grain. The dimensions of this sack have been fixed definitely by law, and the Board understands that importations of sacks are officially passed by Customs officials. The sack is supposed not to exceed the 200lb. limit. In ordinary circumstances new sacks, fresh from the harvester, will not exceed the legal limit. In years of heavy bushel weight, it will depend a good deal upon the effectiveness of the cleaning machinery whether or not the 200lb. limit is exceeded. The chief difficulty, however, arises when grain is cleaned a second time, and particularly when it is graded. In these cases the sacks are slightly stretched when filled a second time, and the removal of the chaff and other light material makes it almost impossible to keep to the legal 200lbs. Consequently the farmer who cleans his wheat, especially the farmer who grades it, must fill the sacks on a weighing machine, and if he does not want to have a slack sack, which is awkward for handling and stacking, he must fold in

the edges when sewing up. The Board feels that in this matter progressive farmers are unnecessarily penalised, and respectfully suggests to the Minister for Customs that the Customs authorities be instructed to accept as legally filled all Chapman sacks, whatever their weight."

#### JUDGING AT SHOWS.

A communication from the Yadnarie Branch directed attention to a paper which had been read before that body by Mr. S. H. Pearce, in which it was contended that a good deal of dissatisfaction which frequently existed with exhibitors could be obviated if judges adjudicated from a set standard for certain definite features, and made the cards with the points scored available to the exhibitors. When the defects of the exhibit were not pointed out, one of the most valuable objects of the show was defeated. He suggested, as an illustration, that the maximum points for dairy cows should be set out as—Appearance 5, age 5, ease of milking 5, &c. A uniform system might be brought about by the Government requiring each society receiving a Government grant to adopt the method recommended. The Branch had resolved that the Board should be requested to bring the subject under the notice of the other branches, and that it should also be discussed at the September Congress. Members agreed that there was considerable substance and soundness in the opinions advanced, but foresaw difficulty in inducing judges to act under such conditions as those outlined. However, they felt that possibly some benefit might be derived from the consideration of the matter by the different Branches, and agreed to adopt the Yadnarie Branch's suggestion in that connection.

#### EASTERN MURRAY CONFERENCE.

A letter from the Wynarka Branch, which last year consented to undertake the arrangements for the 1915 Conference of the Eastern Murray Branches, to be held at Tailem Bend, suggested that, in view of the nature of the past season, and of the agricultural outlook, the fixture should be postponed until 1916. The Board, however, thought that before any definite action was taken, the other Branches ought to be given an opportunity to express their opinions on the proposal.

*Life Membership.*—Mr. James Cook, who had been an active member of the Quorn Branch for a period of approximately 21 years, was appointed a life member of the Bureau.

*New Members.*—The following new members were approved:—Mantung—Wm. Eddy; Parilla—C. B. Davies; Gawler River—G. A. Whittwer, A. C. Goddard; Narrung—J. Steer; Longwood—W. Heard; Ramco—R. Burnell; Tatiara—B. L. Wilkinson; Milang—R. Saltmarsh, P. Bagley, W. Day, D. Turvey; Angaston—M. Hurn, W.

Schwere, W. Patching, W. Mattische, J. P. Richardson; Port Pirie—A. Lines; Mount Gambier—J. Bigham, K. McIntosh, C. Parish; Riverton—L. Jenkins; Wilmington—F. G. Zimmermann; Pine Forest—C. E. Duffield, A. A. Dolling, R. C. Carmen, W. Philby; Waikerie—W. J. Matthews, C. T. Matthews, J. H. Latter, F. L. Watson; Strathalbyn—A. D. James, B. G. Oatley; Riverton—A. E. Rowe, A. Alond; Koonibba—H. Hoffrichter; Sherlock—W. Angas, D. B. Peters, A. Stringer, A. Nurse, H. Smyth, S. Smyth; Roberts and Verran—H. P. Whittaker; Bookpurnong East—J. R. Krame, S. Hannan, W. Flynn, F. Isaacson, R. Rousevell; Morchard—S. Twigden, F. J. Scriven.

### TROPICAL AGRICULTURE.

The Proceedings of the Third International Congress of Tropical Agriculture, which have just been published (London: John Bale, Sons and Danielsson, 10s. net), form a substantial volume of over 400 pages. The volume is edited by the Honorary Secretaries of the Congress, which, it will be remembered, was held last June at the Imperial Institute. This was the first time the Congress had been held in London, and the result was most successful. More than 150 papers, coming from authorities in 50 different countries, were presented to the Congress, and important discussions took place on several of the principal problems connected with tropical agriculture. Abstracts of the papers and full reports of the discussions are printed in the "Proceedings," together with the address delivered by the President of the Congress, Professor Wyndham R. Dunstan, C.M.G., LL.D., F.R.S., Director of the Imperial Institute, and President of the International Association for Tropical Agriculture. Amongst the subjects dealt with in the Proceedings are Technical Education in Tropical Agriculture, Organisation of Agricultural Departments in Relation to Research, Agricultural Credit Banks and Co-operative Societies, Sanitation and Hygiene on Tropical Estates, Legislation Against Plant Diseases and Pests, Fertility of Soils in the Tropics, Variation in Plantation Rubber, Cotton and Cotton Cultivation, Jute and Hemp Fibres, Cereals, Sugar, Cocoa, Tobacco, Oils and Oil Seeds. The Speakers taking part in the discussions included the Right Hon. Lewis Harcourt, M.P. (Secretary of State for the Colonies), Earl Kitchener, the Earl of Derby, Lord Emmott, Sir George Reid, Sir Hugh Clifford, Sir Horace Plunkett, Sir Ronald Ross, Sir H. Hesketh Bell, Sir Sydney Oliver, Sir E. Rosling, and a host of authorities on tropical agriculture from all over the world.

## PARAFIELD EGG-LAYING COMPETITION.

### FINAL REPORT.

The following report on the Egg-laying Competitions, 1914-15, has been forwarded to the Director of Agriculture (Professor Perkins) by the Poultry Expert (Mr. D. F. Laurie) :—

#### CONDITIONS OF THE TEST.

When authority was obtained to organise the year's tests it was considered advisable to make some important alterations in the conditions governing the work. The competition finally consisted of three sections. Four were arranged for, but sufficient entries for section 2 were not forthcoming, and that section was merged in section No. 1.

Section 1.—Open to the world. The chief innovation was the increase in number of birds competing from 6 to 10 in a pen. It was considered desirable for many reasons to ask for the larger number of pullets. Any breeder worthy of the name should be able to make a selection of 10 good pullets from his flock. Fifty-one pens were entered, including 49 pens of White Leghorns, and one pen each of Black Orpingtons and White Wyandottes. It is interesting to note that one pen of White Leghorns and the pen of White Wyandottes were bred in England, and entered by a well-known English utility breeder.

Sections 3 and 4 were arranged under novel conditions. Each pullet was separately housed under the system known as the single-testing method, and which has been fully described in bulletin form.

Section 3 was limited to light breeds only, and there were 34 entries of six pullets each, total 204—all White Leghorns.

Section 4 (General Purpose Breeds).—There were 28 entries, but only 25 entries (150 pullets) were forwarded to the Poultry Station. They included Barred and White Plymouth Rocks, Black, White, and Buff Orpingtons, Silver and White Wyandottes, Rhode Island Reds, Langshans, and Indian Game.

The total number of birds competing in the three sections was 864.

#### WEIGHT OF EGGS.

In conformity with Regulation No. 12, which is as follows :—“ Any pens the eggs from which do not attain an average weight of 24ozs. per dozen by July 31st, 1914, will be ineligible to participate in the prize money, and will be returned to the owners.” One dozen eggs from all the pens in section 1 and four from each pullet in sections 3 and 4 were weighed on July 31st, 1914. The result was that 10 pens in section 1 and 26 birds in section 3 and 51 birds in section 4 were disqualified on account of

light weight eggs. This clearance had the effect of considerably reducing the number of competitors. The disqualified birds in section 1 were returned to their owners, but in sections 3 and 4 the owners agreed to allow the disqualified birds to remain a further period to note if any improvement in weight of eggs was noticeable.

#### IMPORTANT FACTS.

The result in section 1 conveyed no more precise information than was gained in previous tests. As an average dozen eggs, the produce of 10 pullets, were weighed together it was a case of full weight or underweight. Where, as in sections 3 and 4, the eggs of each individual pullet were weighed precise information as to the value of each bird in this regard was obtained. As mentioned in previous reports the disadvantage of pen testing, say, six or ten pullets as against single testing each pullet lay chiefly in the fact that in the case of pen testing it was the average of several birds. In the single-testing sections one can separate the good from the bad at once, and this is the most important point for the breeder. Size of egg is an important commercial point. A small egg is not worth as much from a food point as is a large egg. In most countries eggs are graded to given weights and sold accordingly. Weight and size are characters which can be fixed and improved by careful breeding, and it is important that breeders should have accurate knowledge of the size and weight of the average eggs laid by any hen destined as a breeder. Possibly in some parts of the world the number of eggs laid by competition hens is the main point—at Parafield other factors have due consideration. The knowledge that a pullet in her first year has laid a certain number of eggs is information of great value to the breeder. In pen testing, 6 or 10 pullets, the average may be excellent; but to breed from such birds might be misleading. Two pullets in the pen may have been splendid layers, and some may have been poor layers, and still the average of the pen may have been good. The single pen selects the hen on her merits. The number and size or weight of the egg laid by each become matters of fact.

#### RESULTS AND EGG PRODUCTION.

The eggs laid by the winning pen in section 1 is a very creditable performance. The average per hen is 252.3, which, however, is not a record for the State. The average is from 10 pullets as against six pullets elsewhere. The average of the 34 pens competing is 1,963.1 per pen, or 196.3 eggs per bird.

#### PRIZE WINNERS.

Special Prize (£2 2s.) W. E. Greaves

Section 3 (Single Testing Light Breeds).—The highest score (278 eggs) is to the credit of a hen owned by Mr. D. J. Robertson, of Hamley Bridge. This is an excellent result. It is interesting to note that six pullets laid 250 eggs each and over, viz.:—D. J. Robertson (bird No. 4), 278; C. Hay (bird No. 1), 267; Electricum Poultry Yards (bird No. 4), 257; W. Purvis (bird No. 5), 254; L. F. Dunn (bird No. 3), 252; Electricum Poultry Yards (bird No. 2), 250.

The special prize is awarded to Mr. D. J. Robertson for his entry, No. 17, bird No. 4. In section 3 broodiness disqualified as regards the special prize. None of the prize winners in this section had any case of broodiness recorded; no eggs with tinted shells were observed; the quality of the shell was good, and the eggs were up to standard requirements.

In section 4 there were some excellent scores. This section is confined to heavy breeds, and many of the competitors were standard bred exhibition fowls. Broodiness in this section was penalised to the extent of one point for each case, in regard to the award of the special prize only.

## FOODS AND FEEDING.

The following list of the foods used and their cost make interesting reading. Never in a long experience has the cost risen so rapidly and to such extreme values:—

## Section 1.

|                     |                                                    | £  | s. | d. |
|---------------------|----------------------------------------------------|----|----|----|
| Wheat .....         | 258½ bush. at from 3s. 6d. to 8s. per bush. ....   | 59 | 12 | 4  |
| Pollard .....       | 464½ bush. at from 11½d. to 2s. 5d. per bush. .... | 38 | 18 | 7  |
| Bran .....          | 167½ bush. at from 11½d. to 2s. 5d. per bush. .... | 12 | 16 | 3  |
| Lucerne chaff ..... | 9½ cwt. at 4s. per cwt. ....                       | 1  | 18 | 3  |
| Meat meal .....     | 14½ cwt. at 18s. 6d. per cwt. ....                 | 13 | 5  | 1  |
| Grit .....          | 1 ton 3 cwt. 58 lbs. ....                          | 1  | 7  | 0  |

£127 17 6

The cost of food per hen works out at 7s. 6-3d.

*Section 1.*  
EGGS LAID.

The total number of eggs laid by the final competitors in section 1 is 66,748; in section 3, 27,678; and in section 4, 10,749. The average price for the year April 1st, 1914, to March 31st, 1915, is 12-11d., compared with 11-74d. per dozen last year.

*Section 1.*  
SUMMARY OF RESULTS.

|                                               |                     |
|-----------------------------------------------|---------------------|
| Number of pens .....                          | 34                  |
| Number of hens .....                          | 340                 |
| Total number of eggs laid .....               | 66,748              |
| Total value of eggs laid .....                | £280 13s. 4d.       |
| Total cost of feeding .....                   | £127 17s. 6d.       |
| Profit over cost of feeding .....             | £152 15s. 10d.      |
| Average market price of eggs .....            | 1s. 0-11d. per doz. |
| Average number of eggs laid per hen .....     | 196-3               |
| Average number of eggs laid per pen .....     | 1,963-1             |
| Average cost of food per pen of 10 hens ..... | £3 15s. 3d.         |
| Average cost of food per hen .....            | 7s. 6-3d.           |
| Eggs laid by winning pen .....                | 2,523               |
| Highest average per hen .....                 | 252-3               |
| Profit over cost of food per pen .....        | £4 9s. 10-17d.      |
| Profit over cost of food per hen .....        | 8s. 11-81d.         |

There were during the period under review 103 markets, and the average price of eggs for each month was as follows:—

|           |   |                  |       | <i>s.</i> | <i>d.</i> |           |
|-----------|---|------------------|-------|-----------|-----------|-----------|
| April     | 9 | Markets averaged | ..... | 1         | 4-4       | per dozen |
| May       | 8 | "                | "     | 1         | 6-2       | "         |
| June      | 9 | "                | "     | 1         | 3-4       | "         |
| July      | 9 | "                | "     | 1         | 0-9       | "         |
| August    | 8 | "                | "     | 0         | 9-1       | "         |
| September | 9 | "                | "     | 0         | 8-4       | "         |
| October   | 9 | "                | "     | 0         | 8-0       | "         |
| November  | 8 | "                | "     | 0         | 7-1       | "         |
| December  | 9 | "                | "     | 0         | 8-8       | "         |
| 1915.     |   |                  |       |           |           |           |
| January   | 8 | "                | "     | 0         | 10-1      | "         |
| February  | 8 | "                | "     | 1         | 2-5       | "         |
| March     | 9 | "                | "     | 1         | 4-1       | "         |

The lowest published market price for eggs was 7d., and for seven markets in succession during part of November and December this low price remained. The highest price recorded during the year was on May 28th, when 1s. 8d. was the price. On June 2nd the price receded  $\frac{1}{2}$ d., and thereafter there was a gradual easing.

(To be continued.)

D. F. LAURIE, Poultry Expert and Lecturer.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

### CONFERENCE OF MID-NORTHERN BRANCHES.

*(Continued from page 679.)*

#### POULTRY INDUSTRY AND ITS PROSPECTS.

The Poultry Expert (Mr. D. F. Laurie) delivered an address under the above-named title. He said the principal problem which most poultry keepers had to face now was how to feed and maintain their birds. It might interest them to know that 60 per cent. of the mash given to the poultry at Parafield every day was in the form of green lucerne. This was a splendid fodder for fowls, and helped tremendously to deepen the color of the yolks of the eggs—a matter of considerable importance. Breeders in the northern areas complained bitterly of the heavy mortality among their birds. In 99 cases out of 100 he was convinced that the deaths were due to tick. Only a few days ago at one place he found a large number of tick in a pepper tree, they having hidden themselves under the bark. Every effort should be made to eradicate tick, which constituted a terrible scourge, and a slur on the owners of the poultry troubled by the pest. The prospects of the poultry industry in South Australia had never been brighter than they were to-day, and it therefore behoved them to be ready to reap the benefits which undoubtedly awaited them. He appealed to poultry keepers throughout the State to market only infertile eggs. Through the marketing of fertile eggs, which often were more or less decayed when they reached the consumers, the producers lost approximately £60,000 per annum—a big amount, especially in existing circumstances. It was ridiculous to imagine that it was necessary to have the male birds with the pullets and hens to secure the best results from the latter. Except when run together for breeding purposes the two sexes should always be kept separate. He strongly favored autumn hatching of chickens, for the pullets raised during that period of the year were more vigorous than those hatched in the spring, they laid bigger eggs, and the cockerels were available at a time when the market was practically bare, and consequently the highest prices were obtainable. Farmers who said they could not run poultry on account of the foxes should encompass fairly large yards with wire-

netting to a height of about 6ft. 6in., and put a couple of loose wires at the top. Such a barrier would prevent the slyest and most nimble fox from attacking the birds, which should be provided with galvanized iron shelters, so as not to afford any avoidable accommodation for tick.

#### BARE FALLOWING V. THREE YEARS SYSTEM.

Mr. H. R. Lines contributed the following paper:—"Since the advent of superphosphates, farming has reached a scientific stage, and the occupation requires skill and tact. Having compared the two systems (bare fallow and the three years system), I am in favor of the former for the following reasons:—The action of the summer sun on the upturned fallow, together with careful tillage and rain, provides sufficient humus to ensure a profitable return. At the present time land of the value of £8 to £10 per acre will not permit the owner to leave it lying to be worked on the three years principle. Supposing a farmer has a farm of 600 acres, and half of that area is well worked each season, it will, in the long run, return him more profit than if he only works 200 acres and carries 200 sheep, as suggested by Mr. McEwin in a paper read at the Annual Congress. I cannot see how a farm of 600 acres, 200 acres in crop and 400 of fallow, will carry 200 sheep, with 90 per cent. of lambs, all the year round. Land that is only worked occasionally will not produce the quality of feed that maiden land will. Then again a person with 600 acres generally has boys who have to be employed. The average farmer has two sons, and if only 200 acres are tilled their employment for the year will be scarce, whereas with our usual rainfall while working 300 acres they would be constantly employed. Some people argue that land constantly worked will, in time, become dirty with weeds, but usually the stubble on lea land is left to rot, and all rubbish remains until fallowing time and is then ploughed under, and then may remain in a preserved state until sufficient moisture causes it to grow, usually about seeding time. But with stubble land required for fallowing the stubble is generally burnt first, thus to a large extent destroying a large proportion of rubbish, as well as parasites and any fungus that may happen to be in the land. A sweeping fire over land is a splendid purifier. Then again stubble-fallowed land does not require the strength to work it that lea land does; here a saving is effected. If the rainfall at seeding time happens to be scanty, the most profitable fallow to have is from the first year system, because it is generally finer, and responds to moisture quicker than lea land, and thus better germination is secured. It may be said that in the long run on the third year system the land will remain in better heart than the bare

fallow method, but weeds existing on lea land may have the same deteriorating effect as continual cropping. The main secret of success in the bare fallow principle is the continual working in the right time of the season of the fallow land, which preserves moisture. This system has been practised successfully in Canada and England for a great many years, and experts tell us that land in Australia is equal to that of either of these countries, and the time is fast approaching when agricultural land in Australia will have to be cropped to a far greater extent than in former times. Artificial manures have increased the value of land, and have made it more productive. A few sheep could be carried at a certain period of the year with the bare fallow system, simply to keep down the surplus weeds which may happen to appear after the summer rains. It behoves every grower of wheat to do his utmost to secure the best and quickest return from his land. Our Government recognises the importance of the wheat-producing industry, and are assisting farmers to sow as large an area as possible during the coming year, and rightly so, because it is the most profitable investment of a nation's wisdom and capital."

Mr. G. F. Jenkins differed from many of the conclusions arrived at by the writer of the paper. He had personally adopted the three years system (i.e., bare fallow, crop, and grazing) for a number of years, and had found it most profitable. Whilst they might have an extra 100 acres or so of land under crop when working on the two years system, the former showed more profit when the extra expense involved in cultivation with the two years system was taken into consideration. Most farmers got their lambs off as freezers, and therefore they would not have to be kept for more than six months. If they went in for hand feeding to a small extent the lambs would be off the farm in about five months. He did not approve of burning off stubble. The bare fallow wheat system would in the long run prove a disastrous one.

Mr. Brooks (Booleroo Centre), said the great difficulty with the three years system was to keep the land clean in the spring time. Hand feeding of sheep was, in his opinion, impracticable.

Mr. R. Pavy (Crystal Brook), had secured a great deal more profit by adopting the three years system. The thorough working of the land was a most important factor.

Mr. M. J. McAuley (Georgetown) thought the time of fallowing had a great deal to do with the success of the system.

Mr. G. A. Noll had tried to work his land on the three years system, but found that the land, after being left out for a year, became crumbly, consequently he came to the conclusion that cropping every other year was best.

Mr. Lines, in reply, said he had been working on the two years system for 15 years, and to-day, so far as he could see, his farm was as productive as ever.

## EVENING SESSION.

### Free Parliament.

#### BRANDS ON SUPER. BAGS.

On behalf of the Georgetown Branch, a question was asked as to whether the legislation controlling the sale of super. demanded that the name of the super., in addition to the grade or analysis thereof, should be marked on the bags. The Chief Inspector (Mr. Geo. Quinn) supplied the following reply:—"The only brands required to be put on bags containing fertilisers are set out in section 8 of the Fertilisers Act, 1900. 'Every person who sells or offers for sale any fertiliser shall brand or stamp upon or durably affix to or cause to be branded or stamped upon or durably affixed to every sack, barrel, case, or other package containing any portion of such fertiliser, the name of the manufacturer or vendor, and the figure, word, trade mark, or trade description corresponding to the figure, word, trade mark or trade description stated on the invoice.' From this it will be seen that the quality of the brand of super. must be stated on the invoice, and the brand on the bag implies that the quality of its contents is up to the standard guarantee given for that brand by the maker or seller to the Inspector of Fertilisers. The buyer should see, therefore, that the bags are branded with the seller's trade brand, and that he is given an invoice containing that identical brand with its guaranteed percentage of phosphate or other constituents as the case may be, set out opposite to it."

The same officer said, in reply to a question relating to the sale of chaff in bags containing less than 56lbs.:—"The Sale of Hay and Chaff Acts, 1908 and 1913, sets out a ton of chaff to be 2,240lbs., and if sold by the bag the standard weight of contents must not be less than 56lbs. If a farmer is supplied with light weights he should weigh the chaff on a reliable weighing machine in the presence of reputable witnesses—preferably public officials—and claim for shortage found. If the evidence is conclusive the department could take action also if the farmer is prepared to assist with reliable evidence. In respect to what the Government is doing to enforce the Act, inspectors are 'going about,' and many convictions have been secured for selling light-weight bags, as well as for mixing straw with the hay when cutting, but they cannot be at the elbow of every chaffcutter, hundreds of which are scattered over the State."

The subject of wheat pickling was also discussed.

## POSSIBLE IMPROVEMENTS IN THE FARMING PRACTICES OF THE HUNDREDS OF AYERS AND HANSON.

In addressing the gathering on this subject the Director of Agriculture (Prof. Arthur J. Perkins) said:—"I congratulate the farming community generally on the magnificent way in which they have conducted themselves under most trying conditions. We must all sympathise with them, especially with the younger men, and more particularly those who have started during the past year or so. It is to be hoped that they will take heart from the example of the older farmers.

"In considering possible improvements in the farming practices of the hundreds of Ayers and Hanson, I felt that from statistical sources I should be able to find what actually are the practices of the particular hundreds in question, and I would, therefore, ask you to glance through some of these figures:—

TABLE I.—*Showing Primary Distribution of Land in Hundreds of Ayers and Hanson (1912).*

| Description.                     | Area.<br>Acres. | Percentage of<br>Total Area. |
|----------------------------------|-----------------|------------------------------|
| 1. Privately owned land .....    | 91,438          | 57.47                        |
| 2. Agreement to purchase .....   | 28,017          | 17.72                        |
| 3. Leased Crown lands .....      | 4,281           | 2.71                         |
| 4. Unoccupied Crown lands .....  | 34,344          | 21.73                        |
| Total area .....                 | 158,080         |                              |
| Unoccupied area (holdings) ..... | 122,736         | 78.27                        |

"One particularly notices that out of an area of 158,080 acres, there are approximately 34,344 acres of unoccupied Crown lands, equal to 21.73 per cent. of the total. The bulk of this is taken up with stock routes and forest reserves, only four-fifths of the two hundreds therefore are available for agricultural use.

"In Table II. we see the disposal of the occupied area in 1912. We notice that over 62,000 acres, or over half of the occupied area, has never been broken up, and is merely grazed. The balance comes within the farming areas.

TABLE II.—*Showing Distribution of Occupied Area (1912).*

| Description.                                 | Area.<br>Acres. | Percentage of<br>Occupied Area. |
|----------------------------------------------|-----------------|---------------------------------|
| 1. Under crop .....                          | 30,172          | 24.38                           |
| 2. Bare fallow .....                         | 17,777          | 14.37                           |
| 3. Idle in 1912, previously cultivated ..... | 13,187          | 10.67                           |
| 4. New land cleared .....                    | 422             | 0.34                            |
| 5. Balance, grazed, &c. ....                 | 62,168          | 50.24                           |
| Total area occupied .....                    | 123,736         |                                 |

TABLE III.—*Showing Distribution of Cultivated Area (1912).*

| Description.          | Areas,<br>Acres. | Combined<br>Areas,<br>Acres. | Percentage of<br>Cultivated Area. |

| Peas .....            | —                | 3                            | 0.01                              |

Total cultivated area ..... 47,949

Including bare fallow, nearly 94 per cent. of the total cultivated area is connected with the growing of wheat.

“Table III. shows what sort of cropping was adopted in 1912. The great bulk of the wheat crop was for grain, and the total area under wheat was 27,176 acres, or 56.68 per cent. If we add the 17,777 acres that were under bare fallow, and which would carry wheat in the following year, we find that approximately 94 per cent. of the area cultivated in these two hundreds is practically engaged with wheat. Of the remaining 6 per cent. 3.02 per cent. carried lucerne, 1.81 per cent. sown grasses, 1.15 per cent. oats, .17 per cent. barley, .06 per cent. vines, .02 per cent. orchards, and .01 per cent. peas. This means in effect that we have here a wheat district pure and simple.

“When we are called upon to deal with possible improvements in practices, it is well to form a rough idea of what happens to be the gross revenue under the existing treatment of the land, and so I have endeavored to work it out, adopting what I take to be fair average prices:—

TABLE IV.—*Showing Calculated Gross Revenue from Cultivated Area in 1912.*

| Description.                  | Total<br>Quantities. | Yield<br>per Acre.  | Total<br>Value. |       |
|-------------------------------|----------------------|---------------------|-----------------|-------|
|                               |                      |                     | £               | s. d. |
| Wheat @ 3s. 6d. bushel .....  | 399,982bush.         | 18bush, 37lbs.      | 69,996          | 17 0  |
| Hay @ 30s. ton .....          | 8,795 tons           | 1 ton 8cwts, 32lbs. | 13,192          | 10 0  |
| Oats @ 2s. bushel .....       | 8,111bush.           | 18bush, 33lbs.      | 811             | 2 0   |
| Barley @ 2s. 6d. bushel ..... | 2,462bush.           | 29bush, 33lbs.      | 307             | 15 0  |
| Peas @ 3s. 6d. bushel .....   | 60bush.              | 20bush.             | 10              | 10 0  |
| Straw @ 10s. ton .....        | 17 tons              | —                   | 8               | 10 0  |

Total gross revenue from cultivated area ..... 84,327 4 0

This cultivated area includes grazed lucerne, sown grasses, orchards and vines, the revenue from which is not taken into account in Table IV., i.e., 1,937 acres.

Cultivated area representing 46,012 acres yielded £84,327 4s., or £1 16s. 8d. per acre per annum.

Gross revenue per acre per annum from area under crop (exclusive of bare fallow) would be £2 19s. 9d.

All these figures are exclusive of grazing returns and other side lines open to all farmers.

"The total gross revenue in this case is represented by £84,327 4s. for one year. This corresponds to an area of 46,012 acres, because neither orchards, vines or lucerne have been taken into consideration. This gives £1 16s. 8d. per acre per annum in the way of gross return received from that area. Of course I admit that it does not take into consideration grazing, and other side lines that are open to all farmers.

"Passing to the livestock in the district, it will be seen from Table V. that there are 2,002 head of cattle, 2,493 horses, 3,172 sheep, 186 pigs.

TABLE V.—*Showing Livestock Recorded for Hundreds of Ayers and Hanson in 1912.*

|                         |            |
|-------------------------|------------|
| Cattle (all ages) ..... | 2,002 head |
| Horses (all ages) ..... | 2,493 "    |
| Sheep (all ages) .....  | 30,172 "   |
| Pigs (all ages) .....   | 186 "      |

"As I wish to establish a grazing equivalent of livestock in terms of sheep, I have assumed that one head of cattle is equal to seven sheep. It must be remembered that many of the cattle are young, so that will probably be a fair estimate. The 2,002 cattle, therefore, represent 14,000 sheep. I have assumed that the horses were grazing half their time, making them equivalent to 8,722 sheep, which, with 30,172 sheep, make a total of grazing stock equivalent to 52,894 sheep.

"The area available for grazing is represented by 77,682 acres. This gives a sheep carrying capacity for the district of .68 sheep per acre. To determine the gross revenue from livestock is more difficult than from farm products, because we are dealing with shifting commodities. I cannot therefore claim any great accuracy for the figures given.

TABLE VI.—*Showing Sheep Equivalence of Livestock Grazed in the two Hundreds in 1912.*

|                                                          |                     |
|----------------------------------------------------------|---------------------|
| 2,000 cattle, equivalent to .....                        | 14,000 sheep        |
| 2,493 horses (half-time), equivalent to .....            | 8,722 "             |
| Sheep .....                                              | 30,172 "            |
| <b>Total sheep equivalence of livestock grazed .....</b> | <b>52,894 sheep</b> |

TABLE VII.—*Showing Grazing Area Available in 1912.*

|                                          |              |
|------------------------------------------|--------------|
| Land temporarily out of cultivation..... | 13,197 acres |
| Lucerne .....                            | 1,027 "      |
| Sown grasses .....                       | 868 "        |
| Land occupied but not cultivated.....    | 62,590 "     |

Assumed total grazing area ..... 77,682 acres  
 This represents a grazing equivalent of 0.68 sheep per acre per annum.

TABLE VIII.—*Showing Calculated Gross Revenue from Livestock in 1912.*

|                                       |         |
|---------------------------------------|---------|
| 30,172 sheep at 15s.....              | £22,629 |
| 917 cows (of milking age) at £6 ..... | 5,502   |

Total gross revenue from livestock ..... £28,131  
 From 77,682 acres assumed to be grazed this represents 7s. 3d. per acre.  
 Horses will, of course, return some revenue in the way of sales of youngsters; in general, however, work represents their contribution.  
 Pigs are mainly hand fed, and too small in numbers to affect figures.

TABLE IX.—*Showing Combined Gross Revenue from Cultivated and Grazed Areas, 1912.*

|                                                | £      | s. | d. |
|------------------------------------------------|--------|----|----|
| From 46,012 acres (cultivated) .....           | 84,327 | 4  | 0  |
| From 77,682 acres (assumed to be grazed) ..... | 28,131 | 0  | 0  |

Total gross revenue from combined areas ..... 111,458 4 0  
 This represents 18s. 2d. per acre in way of gross revenue from occupied holdings of the two hundreds.

"I have estimated the gross return from sheep to be 15s. This represents £22,629. The cows, of which 917 were returned as being of milking age, on an estimate of an annual return of £6 per head, represent £5,502, making a total revenue from livestock £28,131. Spreading this over 77,682 acres this represents 7s. 3d. per acre per annum. No account is taken of sales of horses, as the work of the animals generally represents the revenue. Finally, combining both the grazing and cultivated areas, we have for the hundreds 18s. 2d. per acre in the way of gross revenue for the total occupied area.

"This gives a fair picture of what is at present being done in the Hundreds of Ayers and Hanson, and it will be easy for any one so desiring to work out the figures in detail for other Hundreds according to circumstances.

"The outstanding feature is that this area is practically a wheat-growing area for the present.

"If we have to consider anything that is likely to prove an improvement in practice, we must look at it from two points of view, viz., from the point of view of the State, and from the point of view of the individual farmer. These are not always identical, although there is not very much difference between them in the general way.

"In the interests of the State it is required that the land shall return the maximum it possibly can under existing economic conditions. From this point of view, if we take cultivated land, it will be seen to return, in the way of gross revenue, £1 16s. 8d. per acre,

whilst on the other hand the return from grazing land is about 7s. 3d.; for the State the cultivated land is undoubtedly land which is being put to better use. If we have high returns we are producing a large amount of wealth, and therefore contributing to the general welfare of the State. We are also circulating capital in the way of additional wages, and the employment of more men. All these points are of interest to the State generally.

"Naturally, if we look at matters from the individual farmer's point of view the position is somewhat different. From the farmer's point of view an improvement in practice is advantageous only to the extent that it increases his net profits. It is conceivable that 7s. 3d. per acre in the way of gross returns may be more profitable than 16s. 8d., and consequently in dealing with suggested improvements I shall have to bear these points in view. In general, farmers will probably recognise that so long as they can make fair profits from their operations it is to their advantage to produce as much as possible.

"We have seen that these two Hundreds—and I believe it applies very largely to the Lower North—are essentially what-growing areas. The point to be considered under the circumstances is whether wheatgrowing is giving the best possible results. Of course it is quite possible that a combination of other crops may return higher gross returns, and even higher net returns. Wheat, however, is a safe crop, upon which farmers very naturally depend; and it is right that we should first consider the wheat crop from the point of view of possible improvements.

"The first point for consideration is very naturally the existing average wheat yields in the two Hundreds. The results of the past 13 years have been indicated in Table X.:

TABLE X.—*Showing Average Wheat Yields in Hundreds of Ayers and Hanson, 1900-1912.*

| Season.                           | Area under Wheat | Average Yield |      |
|-----------------------------------|------------------|---------------|------|
|                                   | for Grain.       | per Acre.     |      |
|                                   | Acres.           | Bush.         | lbs. |
| 1900 .....                        | 9,066            | 8             | 9    |
| 1901 .....                        | 10,206           | 5             | 45   |
| 1902 .....                        | 9,850            | 7             | 31   |
| 1903 .....                        | 12,107           | 11            | 27   |
| 1904 .....                        | 10,602           | 9             | 18   |
| 1905 .....                        | 12,578           | 14            | 55   |
| 1906 .....                        | 8,998            | 15            | 36   |
| 1907 .....                        | 9,332            | 18            | 53   |
| 1908 .....                        | 11,309           | 20            | 19   |
| 1909 .....                        | 13,076           | 20            | 50   |
| 1910 .....                        | 15,022           | 16            | 24   |
| 1911 .....                        | 17,438           | 16            | 45   |
| 1912 .....                        | 21,489           | 18            | 37   |
| Mean for 13 years (1900-12) ..... |                  | 14            | 11   |
| Mean for 10 years (1903-12) ..... |                  | 16            | 18   |

"If we compare the earlier years of this period—1900-1912—with the later ones, we shall notice that both the area under wheat and the average yield per acre have been more than doubled. It is true that in the latter half seasons have certainly been more favorable; but on the whole, we must admit that improvement in practice has certainly been responsible for some of the results secured. In any case, in my view, seasons have not been particularly favorable since 1909. The average yield is represented by 14bush. 11lbs. for the last 13 years, and by 16bush. 18lbs. for the last 10 years. When referred to a large area, over 20,000 acres, averages of this kind are satisfactory; they include both the skillful and the unskillful, the lucky and the unlucky. In my view these results indicate excellent natural local conditions; and I quite anticipate that a district such as this should average out 20bush. to the acre, good year, bad year. It is merely a question of the more backward ones catching up to the practice of the more progressive farmers of the two Hundreds.

"Although Hanson and Ayers does not represent a hay-growing district, I would like you to glance at the hay average shown in Table XI. :—

TABLE XI.—*Showing Average Wheaten Hay Yields in Hundreds of Ayers and Hanson, 1900-1912.*

| Season.                             | Area under Wheat<br>for Hay.<br>Acres. | Average Yield<br>per Acre.<br>Tons cwt.s. lbs. |
|-------------------------------------|----------------------------------------|------------------------------------------------|
| 1900 .....                          | 3,321                                  | 0 18 101                                       |
| 1901 .....                          | 3,546                                  | 1 0 35                                         |
| 1902 .....                          | 3,576                                  | 0 18 57                                        |
| 1903 .....                          | 3,882                                  | 1 9 22                                         |
| 1904 .....                          | 1,985                                  | 0 15 1                                         |
| 1905 .....                          | 3,038                                  | 1 8 34                                         |
| 1906 .....                          | 2,365                                  | 1 2 76                                         |
| 1907 .....                          | 1,784                                  | 1 1 20                                         |
| 1908 .....                          | 2,827                                  | 1 18 29                                        |
| 1909 .....                          | 3,440                                  | 1 7 55                                         |
| 1910 .....                          | 3,024                                  | 1 2 108                                        |
| 1911 .....                          | 4,023                                  | 1 6 94                                         |
| 1912 .....                          | 5,677                                  | 1 8 32                                         |
| Mean for 13 years (1900-1912) ..... |                                        | 1 4 51                                         |
| Mean for 10 years (1903-1912) ..... |                                        | 1 6 2                                          |

"The area under hay has not increased appreciably within recent years as has been the case with grain crops. This points to the fact

that hay is grown mainly for local consumption. If the average grain yields of the district are good the same cannot be said of the hay yields. I take it that a district that can very well grow 20bush. of grain to the acre can certainly grow 2 tons of hay without difficulty. Probably it will be said that it is the worse crops that are cut for hay in this district, and this would account for the poor yields.

“That is the position in so far as wheat is concerned in the two Hundreds. I assume that those who are securing average results such as have been indicated are well acquainted with what is the best practice in the handling of wheat crops. At the same time I would like to draw attention to one or two points bearing on the matter,

“It will be recognised by everybody that bare fallow before wheat is after all the sheet anchor of farming anywhere in the Lower or Middle North. No doubt it has many advantages, and it will be found that this practice of preceding wheat by a year's tillage is not peculiar to South Australia, but is a phase of farming through which many countries have passed. Not many years ago it was the practice in England, and various parts of Europe, and it continues to be so at the present time to some extent. In these countries, as the population became denser, and as the settlement became closer, land values rose, and it became increasingly necessary to find some means of escape from a practice which allowed one crop to monopolise the land 18 to 20 months. The practice threw two years' rental on the wheat crop, and prevented the farmer making any profit out of the land whilst it was being treated as bare fallow. But whilst it has been possible to do away with bare fallow in many of these countries without direct damage to the wheat crop it is very unlikely that similar results could be achieved over the bulk of our land. Indeed there are very few localities to the north of Adelaide in which bare fallow before wheat is ever likely to be dispensed with. We have therefore to face the fact that crops of wheat will have to be preceded by bare fallow at the present time and probably in the future too.

“In this connection I am able to show from direct experimental data extending over a number of years, that when in our northern districts land ploughed in winter is made to carry a summer fallow

crop, it has the effect of depressing very appreciably both grain and hay yields of wheat in the following year, relatively to wheat grown after bare fallow, pure and simple. These results have been summarised in Table XII.:-

TABLE XII.—*Showing Roseworthy Agricultural College Returns of Wheat grown after Sorghum, comparatively with Wheat after Bare Fallow, 1906-1913.*

| 1913         | ..... | 0                       | 10 20  | 0                           | 12 45  | — 17·91                   |
| Means.       | ..... | 1                       | 18 45  | 2                           | 3 82   | — 12·18                   |

“We see in Table XII. the results of eight years in which the returns from wheat grown after sorghum are contrasted with the returns from wheat after bare fallow, the plots being contiguous. It will be seen from the averages that whilst wheat after sorghum yielded 16bush. 51lbs. to the acre, wheat after bare fallow yielded 20bush. 21lbs., or close on one-fifth better than wheat after sorghum. This presents a difference in returns which it would be difficult for the sorghum crop to make good. As hay returns they had from wheat after sorghum a return of 1 ton 18cwts. 45lbs., whereas from wheat after bare fallow they had 2 tons 3cwts. 82lbs., a difference of 12·10 per cent. I do not say that sorghum crops are of no value, but what I wish to emphasize is that they are not in their place before wheat, because the reduction in yield is too heavy.

"This does not, to my mind, mean that it is quite impossible to put in another type of crop before wheat in special cases. Sorghum, so far as we can see, is harmful to wheat because it seems to drain the subsoil moisture from the fallows in the summer. If we sow a fast-growing crop that can be raised during the winter, and which for want of a better name we may call a fallow crop, we can very frequently raise it without danger to the wheat crop. The type of crop which I have in view is a crop like peas, sown in the early autumn, or white mustard. These crops, if grown on the early rains, do not interfere much with the wheat crop that follows, because they should be fed down before September, thus allowing the ground to be cultivated during the spring and summer months in the ordinary way. I have found this practice of advantage in special cases where feed has been short in winter months. Apart from examples of this sort, so far as I can see, we are not in a position in the Lower North to put another crop before wheat.

"In order to ascertain the extent to which the practice of sowing wheat in bare fallow is in vogue in this district, all that is necessary is to contrast the area under bare fallow in one season with the area under wheat in the following season. This will give the proportion of wheat sown on fallow which has been summarised below for the past 13 years in Table XIII. :—

TABLE XIII.—*Showing Area under Wheat, both for Grain and for Hay, in Hundreds of Ayers and Hanson, comparatively with Area treated as Bare Fallow in the preceding Seasons, 1900-1912.*

| Season.    | Area under<br>Wheat for<br>Grain and Hay. | Area under<br>Bare Fallow<br>in Preceding<br>Seasons. | Percentage of<br>Area of Crop<br>Sown on Bare<br>Fallow. |
|------------|-------------------------------------------|-------------------------------------------------------|----------------------------------------------------------|
|            | Acres.                                    | Acres.                                                |                                                          |
| 1900 ..... | 12,387                                    | 5,396                                                 | 43.56                                                    |

| 1908 ..... | 14,136                                    | 11,023                                                | 77.98                                                    |
| 1909 ..... | 16,516                                    | 11,281                                                | 68.30                                                    |
| 1910 ..... | 18,046                                    | 12,253                                                | 67.90                                                    |
| 1911 ..... | 21,461                                    | 15,092                                                | 70.32                                                    |
| 1912 ..... | 27,166                                    | 14,582                                                | 53.68                                                    |

"Whilst in 1900 there were 12,387 acres under wheat, in the preceding year there were only 5,396 acres under bare fallow. This means that not half the crops were sown on bare fallow. Although the figures improve somewhat, with the very noticeable exception of

1912, when new areas were opened, I am forced to the conclusion that farmers in this district do not hesitate in taking second crops of wheat from their land. Probably the same practice obtains in other parts of the Middle North. There is no doubt that a second crop is sometimes in certain conditions, satisfactory; that is to say, one gets payable returns from it. I think, however, that from a general point of view to take successive wheat crops off the same land is mistaken policy. If there is one method that helps the spread of diseases, such as smut and takeall, it is this practice of making wheat follow wheat year after year on the same plot of land. But apart altogether from this point of view so far as wheat is concerned, between harvest and seeding time there is never under our conditions of climate sufficient time to permit of the land being got into sufficiently good order to ensure good average yields.

“Hence, although I think it a mistaken policy to make wheat follow wheat, I am of the opinion that we shall be taking fuller advantage of our bare fallow if we adopt a second crop after wheat, providing that second crop is not wheat. This is an improvement which is likely to be of use if it is adopted in these districts.

“I have had occasion to speak about growing barley as a second crop before, and I would like to say a few words on this. There are two crops which are available to us in this connection, namely, barley or oats, according to which is best suited to any particular district. Either one or the other is better than wheat after wheat, and in Victoria already it will be found that it is a very common practice to find bare fallow, wheat, oats—a form of rotation frequently used in Europe. South Australian farmers sometimes object to barley as a crop, on the ground that it dirties their land, introducing barley into their wheat fields; in my experience this difficulty can easily be avoided if care is taken in cleaning farm machinery and the barley is not fed whole to the horses. At Roseworthy Agricultural College, although for the last 10 years we have always grown approximately 100 acres of barley a year, we have had very little barley in our wheat crops.

“Another objection to this grain is that when it is produced in any quantity there is no market for it. This is true up to a certain point. Barley, however, is one of those commodities that can be exported quite as well as wheat, and it is only necessary for the State to have an exportable surplus to ensure a market in this way. The imports into Great Britain during the past five years have amounted to between 45,000,000 and 46,000,000 bushels per annum, the bulk of which

comes from the Mediterranean. The total export of wheat from the Commonwealth is only about 30,000,000 bushels; if therefore Great Britain can absorb our wheat she can do likewise with our barley. Even if barley could not be exported there is no cheaper foodstuff that can be used for sheep or pigs, and in spite of the local prejudice against it, it is a very satisfactory foodstuff for horses. There is the additional advantage, too, that barley does not require the careful tillage that wheat needs. It is able to make way against weeds, even if rain does not germinate them on the stubble. Many of these advantages can also be claimed for oats. The only trouble is that oats have to be sown earlier, and the result is that frequently there is not sufficient germination of weeds to clean the land, and oats in their early stages cannot make headway against rank weeds.

“Forage crops could be grown in the place of these cereals if it is thought desirable. I admit that so far as the Lower Northern conditions are concerned suitable forage crops are rather rare, but there are some that we know to be useful.

“Some are becoming known; peas for example are grown fairly extensively. Another very fair forage crop in certain districts is lucerne sown in the wheat crop, not for cutting, but for grazing for three years or thereabouts. In certain seasons both rape and kale are good, but both these crops always need early seeding conditions, and it is not often we get early seasons. Mustard is probably better than rape or kale, because it grows faster, and can therefore be sown later without disadvantage. If we take the practice general in the Lower Northern area, of alternate cropping and bare fallow, unless there is a fairly large number of livestock on the farm there is no call for forage crops, nor is there any means of utilising profitably land that is left out of cultivation. In the course of years constant bare fallow will tend to reduce the natural fertility of the land, since there is no better means of destroying organic matter present in the soil than to treat it as bare fallow year after year. The air acts upon it, and if the destruction of organic matter were complete, the soil would be little better than a mixture of ground bricks and sand. It is difficult to notice this action, as it is a most gradual process. The difference in the nature of the soil from one year to another is not very great, but there comes a time when it is difficult to handle the land, because of its defective mechanical condition. There are various ways of avoiding this undesirable state of affairs. Sometimes in other countries the land is put under timber for a number of years. Green manuring is also practised, but from our point of view the simplest and cheapest method consists in

allowing livestock to graze over our fields in as great numbers as is consistent with reasonable profits. Their excreta will return to the soil quantities of organic matter quite equal to those destroyed in the bare fallow process.

"I have indicated in Table XIV. the average weight of the droppings of various forms of livestock over a year's time.

TABLE XIV.—*Showing Average Quantities of Manure Dropped by Grazing Livestock per Annum.*

|              |                          |
|--------------|--------------------------|
| Cattle ..... | 10 to 12 tons per annum. |
| Horses ..... | 7 to 8 tons per annum.   |
| Pigs .....   | 1 to 1½ tons per annum.  |
| Sheep .....  | ½ to ¾ ton per annum.    |

We gather, then, from Table XIV., that if we have farm land carrying two or three sheep to the acre, which is well within the capacity of farm land in the area under notice, we get practically a dressing of organic matter of from one to two tons per acre per year. If sheep kept under these conditions only just pay for themselves by the sale of their wool and lambs, and give this dressing in addition, it is of advantage to have them on the farm. From this point of view one of the improvements that most of the Lower Northern farmers can take up with great advantage to themselves is to increase the number of livestock on their holdings.

"It is sometimes said that grazing livestock impoverishes the land, because the animals must take away in their bodies something which they have taken out of the soil. Whilst this seems logical enough, experience shows that it is not so. Land that is left out as pasture for any length of time gains in fertility. This gain in fertility, whilst it is partly due to the coating of organic matter spread over the surface, is also due to the mineral matter taken up from the depths of the soil by the roots of plants and placed in the surface layers, where the young roots of the crop draw their earliest nutriment.

"In Table XV. I have shown what are the percentages of useful minerals retained in their bodies by fattening livestock. It will be seen that this drain is not very great, varying from 1 per cent. to 20 per cent., according to circumstances; the great bulk of it is returned to the soil in the form of excreta. Additionally, the excreta brings organic matter which is derived very largely not from soil materials, but from the elements of water and the atmosphere.

TABLE XV.—*Showing Percentages of Minerals in Foodstuffs retained in Fattening Increase of Livestock, and Percentages returned to the Soil in Excreta.*

| Description.          | Percentage Retained<br>in Fattening Increase. | Percentage Returned<br>to Soil in Excreta. |
|-----------------------|-----------------------------------------------|--------------------------------------------|
| Nitrogen .....        | 5 to 13 ..                                    | 87 to 95                                   |
| Phosphoric acid ..... | 10 to 20 ..                                   | 90 to 90                                   |
| Potash .....          | 1 to 4 ..                                     | 96 to 99                                   |

The percentage retained would be lighter for young growing livestock.

"Hence we can realise how it is that grazing enhances the natural fertility of the soil.

"I should like to say a few words on the question of hand-feeding. A few years ago anyone mentioning this subject would have been laughed at. Hand-feeding is nevertheless practised for all livestock in other countries. The point is that we cannot keep a reasonable number of livestock on the farm unless we are prepared to hand-feed them at some time or other of the year. I think it can be shown that if livestock are going to return the prices that they did before these troublous years, hand-feeding will be profitable even on small areas of land. Land that can carry one sheep to the acre will produce, say, two tons of hay without difficulty. This quantity of two tons of hay, assuming that the sheep will consume about 2lbs. a day, will keep six sheep for a year. It then becomes a question as to whether the six sheep would return a greater net profit than could be secured if the hay had been sold at ordinary rates. It is actually possible to hand-feed sheep from one end of the year to the other without losing money; this, however, is never necessary. Chaff is a good feed, but it is somewhat difficult to handle. Fortunately for us, in this country elaborate housing of livestock is not needed. However, many parts of South Australia are particularly windy, and it is, therefore, necessary to provide special feeding troughs for the chaff. Secondly, in many cases we shall find that grain is more convenient, and cheaper to feed than chaff. The trouble with the feeding troughs is that they have to be fairly large, otherwise a strong sheep will take command of the troughs, and the weaker animals will be unable to get a share. Where one is feeding grain it can be lightly scattered on the ground, and the sheep will pick up every grain. Wheat, barley, and oats can be used in this fashion. The need of hand-feeding should be foreseen early—it is bad policy to start too late, when the animals have already lost condition. One half-pound of grain, provided that there is a fair picking in the field, is all that is necessary for sheep. Of course, if the sheep have nothing else, they will eat more than 1lb. per day; this, however, is a contingency that one should always aim at avoiding.

"By way of summarising possible improvements in farming practices, I think, in the first place, that whilst the area under wheat should not be reduced in these districts, there are other crops that can be grown in conjunction therewith. I think that the average yield of wheat might be considerably increased in many cases. There are various ways in which the yields can be raised. The fallow should be well worked, better seed should be used, and more super. should be applied to the ground, particularly when they were going in for grazing, and in certain years they might also use a little nitrate of soda. Another practice that should be given particular attention to is the harrowing of crops, particularly after wet winters. Then in order to increase the gross revenue from the soil, a second crop, but not wheat, can be grown with advantage. Then comes the point of increasing the livestock. It is unwise for the farmer to say that he will only keep as many stock on the farm as he can keep at the worst time of the year. The ideal at which one can aim on most farms is a sheep to the acre on the whole area. One might not be able to realize it straight away, as one has to improve the fences, and make provision for water, and so on. Further, it is necessary to learn to handle sheep on small holdings, but it can be done with a very moderate amount of hand-feeding.

"Before closing my address I wish to draw attention to the type of experimental work that I wish to carry out at Booborowie. I hope that many of you will take the opportunity of visiting the experimental farm there. I do not see why one of the conferences should not be held at Booborowie when the occasion arises."

TABLE XVI.—*Showing Proposed Permanent Scheme for Experimental Rotations at Booborowie Experimental Farm.*

- I. (1) Bare fallow, (2) wheat.
- II. (1) Sorghum, (2) wheat.
- III. (1) Bare fallow, (2) wheat (no manure), (3) grazing.
- IV. (1) Bare fallow, (2) wheat ( $\frac{1}{2}$ wt. super.), (3) grazing.
- V. (1) Bare fallow, (2) wheat (1wt. super.), (3) grazing.
- VI. (1) Bare fallow, (2) wheat (2cwts. super.), (3) grazing.
- VII. (1) Bare fallow, (2) wheat (3cwts. super.), (3) grazing.
- VIII. (1) Bare fallow, (2) wheat, (3) barley.
- IX. (1) Bare fallow, (2) wheat, (3) oats.
- X. (1) Bare fallow, (2) wheat, (3) peas.
- XI. (1) Bare fallow, (2) wheat, (3) rape.
- XII. (1) Bare fallow, (2) wheat, (3) barley, (4) grazing.
- XIII. (1) Bare fallow, (2) wheat, (3) oats, (4) grazing.
- XIV. (1) Bare fallow, (2) wheat, (3) lucerne, (4) lucerne, (5) lucerne.
- XV. (1) Bare fallow, (2) wheat, (3) rye grass, (4) rye grass.
- XVI. (1) bare fallow, (2) wheat.

TABLE XVII.—*Showing Proposed Permanent Scheme for Experimental  
cultivation of Wheat at Booborowie Experimental Farm.,*

*Depth of Ploughing* (bare fallow, wheat, 2cwts. super.).—

- I. Fallowed 3in. deep.
- II. Fallowed 6in. deep.
- III. Fallowed 9in. deep.
- IV. Fallowed one year 9in., and two years 3in.

*Treatment of Fallows.*—

Early fallows (June-July).—

- I. Plough 6in., harrow immediately afterwards, and cultivate subsequently according to requirements.
- II. Plough 6in., leave rough in winter, and cultivate subsequently according to requirements.
- III. Plough 6in., roll immediately after ploughing, and harrow or cultivate according to circumstances. Cultivate subsequently according to requirements.
- IV. Plough 6in., skim cross plough after first rain. Cultivate subsequently according to requirements.

Late Fallow (September).—

- V. Plough 3in. deep, and cultivate according to requirements.
- VI. Plough 6in. deep, roll heavily the same day as ploughed, and cultivate subsequently according to requirements.

Autumn Ploughing (March-April).—

- VII. Plough 4in. deep, and roll immediately. Cultivation according to requirements.

TABLE XVIII.—*Showing Proposed Permanent Scheme for Wheat Manure  
Plots at Booborowie Experimental Farm.*

- I.  $\frac{1}{2}$  cwt. superphosphate.
- II. 1 cwt. superphosphate.
- III. 2cwts. superphosphate.
- IV. 2cwts. superphosphate (1cwt. to depth of ploughing at fallowing time, and 1cwt. at seeding time).
- V. 3cwts. superphosphate.
- VI. No manure.
- VII. 1cwt. superphosphate and  $\frac{1}{2}$  cwt. nitrate of soda.
- VIII. 2cwts. superphosphate and  $\frac{1}{2}$  cwt. nitrate of soda.
- IX. 1cwt. superphosphate and  $\frac{1}{2}$  cwt. sulphate of ammonia.
- X. 2cwts. superphosphate and  $\frac{1}{2}$  cwt. sulphate of ammonia.
- XI. 1cwt. superphosphate and  $\frac{1}{2}$  cwt. sulphate of potash.
- XII. 2cwts. superphosphate and  $\frac{1}{2}$  cwt. sulphate of potash.
- XIII. 2cwts. superphosphate,  $\frac{1}{2}$  cwt. nitrate of soda, and  $\frac{1}{2}$  cwt. sulphate of potash.
- XIV. 1cwt. superphosphate.
- XV. No manure.
- XVI. 1cwt. basic slag.
- XVII. 2cwts. basic slag.
- XVIII. 10 tons farmyard manure.
- XIX. 10 tons farmyard manure and 2cwts. superphosphate.
- XX. 10 tons farmyard manure, 2cwts. superphosphate, and  $\frac{1}{2}$  cwt. sulphate of potash.
- XXI. 2cwts. superphosphate and 5cwts. lime.
- XXII. 2cwts. superphosphate and 4cwts. gypsum.

## THE AGRICULTURAL BUREAU.

### CONFERENCE OF LOWER NORTHERN BRANCHES.

The annual conference of the Lower Northern Branches of the Agricultural Bureau was held at Riverton on Thursday, March 11th. Among those present were the Minister of Agriculture (Hon. T. Pascoe, M.L.C.), the Superintendent of Experimental Work (Mr. W. J. Spafford), the Dairy Expert (Mr. P. H. Suter), the Government Veterinary Lecturer (Mr. F. E. Place), Messrs. F. Coleman (vice-chairman), G. Jeffrey, and C. E. Birks (members of the Advisory Board of Agriculture), H. J. Finnis (acting secretary of the Board), and the following delegates from the individual Branches:—Riverton—Robert H. Cooper, J. Elliott Kelly, J. McInerny, J. E. Hannaford, L. Longbottom, H. E. Mills, K. Gray, H. Davis, H. L. Eyre, A. E. Rowe, J. H. Castine, O. E. Longbottom, T. Schultz, W. H. Davis, D. Kieth, J. W. Kelly, H. A. Davis, Alfred Hannaford, Robert J. James, W. B. Davies, E. A. Gray, W. Fisher; Balaklava—B. R. Banyer, C. W. Mills, H. L. Twartz; Leighton—William H. Lloyd; Burra—H. H. Thomas; Gawler River—F. E. Winckel, William Rice; Saddleworth—T. H. Eckermann, F. H. Kelly, W. H. Ashton, P. Manning; Julia—D. S. Heaslip, W. H. Neal, J. Dunstan; Mallala—A. E. Temby; Stockport—J. Howard, Robert Whitelaw.

### WELCOME TO VISITORS.

The Chairman of the local branch (Mr. W. B. Davis) presided, and extended a hearty welcome to the visitors, whose presence, he said, was exceedingly pleasing to himself and to his fellow-members. Having directed attention to the numerous samples of lucerne and other summer fodders, which eloquently, though mutely, testified to the splendid capabilities of the local soil under irrigation, and to the big sheaves of wheaten hay and bags of grain, which showed what the land could do in the way of cereal production, even with such a scanty rainfall as that recorded last season, he introduced the Minister of Agriculture (Hon. T. Pascoe), and invited him to declare the conference open.

### HELPING THE FARMERS.

The Minister was accorded a rousing reception. He apologised for the absence of the Director of Agriculture (Professor

Perkins), who, like the Secretary to the Advisory Board (Mr. G. G. Nicholls), had found it impossible, owing to the demands of other special duties, to attend the conference, much as he would have been pleased to do. In the place of the Director, however, they had with them the Superintendent of Experimental Work (Mr. W. J. Spafford), who, after years of efficient service at Roseworthy College, had been recommended by the Director to the public as one of the leading experimentalists in South Australia. They would all agree with him, he felt certain, that Professor Perkins had sent along a very worthy substitute. Besides Mr. Spafford, there was the Dairy Expert (Mr. P. H. Suter), and the Advisory Board was represented by Messrs. F. Coleman (vice-chairman), G. Jeffrey, and C. E. Birks. It spoke well for the keen interest which those latter gentlemen took in their work that they were prepared to sacrifice their own private affairs to attend conferences of that nature.

They would not be surprised if, on such an occasion, his address should be slightly tinged with the color of existing circumstances, the like of which the State had never before known, and, they fervently hoped, would never witness again. One could not easily exaggerate the importance of the next few weeks to the agricultural community. It depended upon the character of the opening of the season whether the present trouble would be accentuated or not. If there should be an early "break," the losses of stock would not continue much longer; but if, unfortunately, as had happened in the last two or three years, it occurred late, then the agriculturists and the pastoralists would inevitably be put to a tremendous expense to keep their stock alive. The price of fodder was rising almost every day, and the problem of securing adequate supplies, even at the enhanced figures, was becoming increasingly serious. In the circumstances they would realise to some extent the enormous strain which was being imposed upon the Agricultural Department in relieving the prevalent distress, and meeting the requirements of the stockowners who had been unable to obtain fodder themselves.

Owing to the peculiar conditions which existed last year, after the declaration of war, Parliament gave the Government strong powers to enable it effectively to cope with the grave situation—powers the like of which had never before been given to any Government since the foundation of the State. Those powers the Government had sought to employ in the best interests of all concerned, and so that justice should be done to everybody. A number of them were provided so that the agricultural industry, upon which the welfare of the State so largely depended, should not be called upon

to suffer more than could be possibly helped. If it had not been for the powers thus made available, and for the splendid manner in which the officers of the Crown Lands Department and of the Agricultural Department had worked during the last six months, probably 1,000,000 acres less would have been seeded during the coming season than now promised to be the case. He did not think many farmers realised the full magnitude of the relief which the State had afforded, or the enormous drain which that relief involved upon the Treasury. It had to be remembered that the Government was operating in the face, not only of a bad season in South Australia, but also in the face of outside conditions which rendered it impossible to go into the world's market and obtain money with which to finance undertakings. That meant that before any appreciable expenditure could be sanctioned, the reason for it had to be most carefully and thoroughly scrutinised. Had it been possible to secure a loan from abroad, possibly considerably more might have been accomplished than could be achieved under the present disabilities.

They would probably recollect that the two departments to which he had referred had entered upon their campaign of assistance to the men on the land in June or July last, when they materially facilitated the removal of starving stock, especially milch cows, from the Upper Northern districts to the south. Altogether some thousands of animals were shifted, and subsequently returned to their homes, a task which was not made the easier by the fact that in many instances the stock had had to be dealt with in lots of twos and threes. The finding of agistment had been a difficult matter, and all things considered, it was highly gratifying that so few head had been lost. The whole business constituted a fine tribute to the enthusiasm and ability of the officers responsible—his own Secretary (Mr. W. L. Summers) and Mr. Suter. Those gentlemen undoubtedly merited the deepest thanks of the northern farmers. Yet all that had been done in connection with the removal and agistment of that stock could be regarded only as a small thing compared with what was being performed now through the agency of the Drought Relief Board and the Grain and Fodder Board, the former associated with the Crown Lands Department, and the latter with the Agricultural Department. The members of these two important bodies were doing a tremendous work, although in ordinary circumstances the officers who comprised them had ample to keep them fully occupied.

A good deal had been heard lately concerning the way in which the Grain and Fodder Board had obtained the wheat which it had

handled and was still busily engaged in distributing. Parliament gave the Board the power to buy wheat, and if it could not secure all it wanted, to seize grain, always provided that a fair market price should be paid for it. Some people were blaming the Board, and through it the Government, for not having seized all the merchants' wheat. From the standpoint of the agriculturists, as well as from that of the public, he believed that the Board had acted wisely in determining not to adopt the policy indicated—in the first place because of the people's bread, and secondly because if it had made a wholesale seizure of the merchants' wheat—which, by-the-way, would have been the simplest and easiest course to pursue—the wheatfields of the State next season would probably have been thrown into a condition of chaos. All the grain, it must be borne in mind, had been mixed up in the stacks, higgledy-piggledy, so that its use for seed purposes would have meant having crops in all stages of growth, some parts ready to strip, others just fit for the binder, and others again scarcely out in ear, and all jumbled together. The Board had decided that it would be better to buy the 800,000bush. of seed required from the farmers themselves, so that wherever possible named varieties could be distributed, and the interests of the growers thereby studied and safeguarded. The Board had bought as much as it could secure, but a couple of weeks ago it was obliged to seize a quantity of grain in the hands of farmers and others. Other State Governments had seized all the available supplies of wheat, but it was apparent that the adoption of that course had not made any material difference in the price of the loaf of bread. It was a significant commentary that bread was very little dearer in South Australia to-day than it was in New South Wales, although it was necessary to import grain into this State, whereas New South Wales was in a position to export. What was more, the whole business in connection with the wheat problem had been conducted with infinitely less friction in South Australia than in any other State in the Commonwealth.

The Government was engaged in three classes of relief work. It was buying wheat and letting the needy farmers have supplies for seed at a price which, so far, had not averaged 7s. a bushel, let alone 8s., as some individuals asserted it would cost. No interest or principal was asked for until after next harvest. Should a good season be experienced—and they earnestly hoped it would be, and a good price would rule for wheat—as was highly probable—it would not be very difficult for the farmers to meet their obligations to the State. If, however, things did not pan out so well as was expected, and the farmers found themselves unable to foot the bill, then all

they would be required to pay would be interest on the loan represented by the value of the wheat. In some cases the farmers were purchasing their requirements direct from neighbors and others more happily situated; but wherever desired, the Government was standing at the back of the buyers, and allowing the same privileges as though the Board itself was supplying their needs. Then there were the farmers who were able to pay, but could not get wheat for seed. So far as possible the Board would meet their requirements in that respect on a thoroughly reasonable basis. One of the tasks which had engaged the attention of the Board was the purchase of fodder. The latest statistical returns showed that had the State relied upon itself there would not have been sufficient fodder to carry it beyond June or July at the most. The Grain and Fodder Board had therefore purchased more than 30,000 tons of various fodders, and in doing so, be it noted, had not caused the local prices to advance, for the very substantial reason that it had imported more than 25,000 tons from outside the State.

When the assistance afforded by the Government, including reduced freight on the railway for cattle and seed wheat, the distribution of seed wheat to needy farmers, and the forgiving of rents to Crown lessees for 12 months, was summed up, it would represent a temporary loss to the State of more than £1,000,000. Yet they were told by some persons, without much responsibility, it was true, that the Government was doing nothing for the State. He thought all fair-minded observers would admit that the Government had done all that it could safely do, and probably more than had been accomplished in any of the other States. The concrete effect would be that the suffering of the people on the land would be greatly minimised, and that, given a good season this year, and satisfactory prices, the farming industry would be in a more profitable and prosperous condition than it had ever been in before at the close of a droughty period. A drought such as they were passing through was not altogether an unmixed evil, because it stimulated them to become better farmers. It was exceedingly gratifying to him to see such a large attendance at that, the first conference of the Lower Northern Branches of the Bureau. That district was one of the best in the State, and he looked forward to the local farmers, who possessed greater advantages than those in most localities, helping materially to solve the problems which confronted the agriculturists, and thus assisting to increase the productiveness of the soil. It had been very pleasing to notice here and there, in the vicinity of the township, little plots of lucerne. Some might say that such plots were not needed in ordinary seasons,

but he contended that they had a great value, and would pay for themselves over and over again. As an aid to the maintenance of the health of the livestock their usefulness could not be over-estimated. He was convinced that the Board had acted properly in dividing the old Northern Bureau District into two separate districts. (Mr. F. H. Kelly—"That was one of Mr. Nicholls's good suggestions.") Mr. Nicholls had proved himself to be a capital administrator and organiser, and had certainly done wonders for the Agricultural Bureau, and the branches affected would greatly benefit thereby.

#### VISITORS ENTERTAINED.

The local branch entertained the Minister, the experts, the members of the Advisory Board, and the visiting delegates at luncheon at the Central Hotel. A short toast list was honored, and in the course of the speeches the Branch was warmly thanked for its hospitality.

#### IMPROVED DAIRY RETURNS.

"Important factors to observe in order to secure improved dairy returns" was the title of an address given by the Dairy Expert Mr. Suter pointed out with characteristic forcefulness that if only the farmers would grow more stuff of the kind exhibited on the platform, and give it to their dairy cows, they would soon get rid of that bugbear known as "dry bible," which was due to nothing more or less than starvation. Lucerne was a medicine and a tonic, as well as a rich milk producer, and it was within the reach of every owner of stock who had a supply of water at his disposal. With a plot sufficiently large in the spring time they could conserve as silage a considerable quantity of the succulent and palatable fodder for use in times of scarcity. Farmers had been obliged to adopt better methods of cultivation, and it was equally necessary that they should adopt improved methods in their dairying enterprises. Unfortunately many had taken too little interest in their cows, and had left these to the womenfolk to look after.

Essential factors to profitable practice included judicious breeding, feeding, culling, and general management. At present sufficient consideration was not given to the capacity of the dairy cows to produce milk and butter economically. Investigations had proved that there were many cows in South Australia returning products of a value less than the cost of their keep, covering food and labor. Altogether there were 100,000 cows in the State, and he was positive that the great majority of them, if carefully tested for results, would quickly have the death sentence passed upon them. It was quite safe to say that the increased returns which would

follow the raising of the standard of the herds would be almost sufficient to wipe off the loan of £1,000,000 which the State had made, and was making, to the farmers in the form of drought relief. Two points which required special emphasis in the building up of a dairy herd, to secure greater profits, were the selection of a suitable sire, and the elimination of the unprofitable cows by keeping records of the individual production. For some inexplicable reason the testing of the herds was regarded with a lot of suspicion by many farmers, and with one or two exceptions practically nothing had been done by them in that direction in this State. It was utterly impossible for a man accurately to gauge the capacity of his cows, except by means of the scales and the Babcock tester. It was not always the cow that gave the heaviest flow of milk immediately after calving which furnished the most satisfactory financial return over the whole of the lactation period. The good average cow frequently proved to be the more profitable.

There was no doubt that the lack of interest in the matter of testing was attributable in a large measure to the more or less droughty conditions prevalent, and the isolation of the herds. It was much preferable that an independent person rather than the dairyman should keep the records, for in the latter case want of enthusiasm would often materially reduce the value of the results. Furthermore, the records made by the owner naturally would not carry as much weight as those made by an outsider. However, in the north, where the farms were very scattered, he suggested that the owners should undertake the compilation of the records, rather than continue merely to guess the yields obtained from the cows. But in the south-east he strongly recommended the farmers to form herd-testing associations, and to appoint one man to look after all the records, thus ensuring reliable data being collected. Periodical comparisons of the particulars for the different farms would have a stimulating effect upon those whose returns revealed special need for improvement. To illustrate the differences which occurred among individual cows, he quoted the records of the five best animals and the five worst in a herd of 32. These were as follow:—

FIVE BEST COWS.

| No.     | Gallons<br>of<br>Milk. | Fat<br>Test.<br>% | Butter.<br>lbs. | Value.<br>£ s. d. |
|---------|------------------------|-------------------|-----------------|-------------------|
| 1 ..... | 697                    | 4.2               | 326             | 13 11 8           |
| 2 ..... | 641                    | 4.2               | 300             | 12 10 0           |
| 3 ..... | 630                    | 4.2               | 295             | 12 5 10           |
| 4 ..... | 683                    | 3.6               | 271             | 11 5 10           |
| 5 ..... | 531                    | 4.5               | 268             | 11 3 4            |

## FIVE WORST COWS.

| No.     | Gallons<br>of<br>Milk. | Fat<br>Test.<br>% | Butter.<br>lbs. | Value.<br>£ s. d. |
|---------|------------------------|-------------------|-----------------|-------------------|
| 1 ..... | 471                    | 3.2               | 165             | 8 19 2            |
| 2 ..... | 359                    | 3.8               | 151             | 6 5 10            |
| 3 ..... | 347                    | 3.8               | 146             | 6 1 8             |
| 4 ..... | 365                    | 3.6               | 145             | 6 0 10            |
| 5 ..... | 279                    | 3.7               | 122             | 5 1 8             |

The butter yields of the five best cows averaged 292lbs., against 145 4-5lbs. of the five poorer animals. Reckoning the cost of the keep at £6 a head, and the value of the butter at 10d. a lb., the leading quintet showed a profit of £6 3s. 4d. a head, and the others a profit of only 1s. 10d. a head. On that basis, 20 cows equal to the best would show a net profit of £123 6s. 8d., whereas a similar number of the others would give a margin of only £1 16s. 8d. Those figures strikingly indicated the tremendous deficiency represented by a large proportion of the cows in the State. If only 50,000 of the cows reached the standard of the more efficient animals referred to, a net profit of £308,333 would be gained. From 676 cows giving a net return of £6 3s. 4d. a head they would make as much actual profit as could be derived from 100,000 of the inferior type. The average yield per cow in South Australia was 131lbs. of butter, which, at 10d. a lb., would not return £6, so that the owners actually were losing money. The milking of unprofitable cows contributed to the drudgery often associated with the dairying industry, and this was accentuated by the bad arrangement of the milking yard, &c. It was pleasing to reflect, however, that in the latter respect a big improvement had been effected by the South Australian farmers in the last few years. The shortage of labor complained of occasionally could be met if farmers engaged more in dairying, so that they could keep their good men on the farm all the year round, and thus have them available at all times. One of the paramount needs of the time was the grading up of the herds. This work was proceeding at Narrung, in the lakes district, where shortly after the closer settlement of the land the settlers made an arrangement under which they combined to purchase good bulls, and to keep as near as possible to one good breed. The effect of that policy was seen now, as in that district there was a finer class of dairy cattle than he had seen in any other district in the State. The result had been obtained through the transmission of the superior qualities of the sire.

He strongly condemned the practice of breeding from half-bred sires, or those which had pedigrees, but whose ancestors had not come from deep-milking strains. A man with the best intentions

might introduce a pedigree bull into his herd, yet in doing so only "beef away" the milking qualities already possessed. The axiom that the bull was half the herd was very true, because half his and his ancestor's blood was infused into all his progeny, and therefore exerted an enormous influence. He complained that farmers did not attach sufficient importance to the value of stock bred by dairymen who imported animals at heavy cost, and kept records of the performances of the animals. If economy was to be practised anywhere in the dairy business it should be anywhere but in the price paid for the bull. Heavy milking cows could be produced only by purity in breeding from strains with good dairy records. The present was an opportune time for farmers to secure better bulls. Just now the old bulls would bring anything from £4 to £15 in the beef market, according to condition. During the past 18 months more than 2,000 bulls had been slaughtered. Realising the necessity for a source of supply of pure-bred dairy sires, with proved milk and butter ancestry, the Agricultural Department had inaugurated a system of testing and recording the milk and butter performances of dairy stud stock. At least two herds were now being dealt with officially, and it was open to others to benefit similarly. The value of the movement lay in the fact that it would enable buyers to secure young pure-bred sires from cows showing profitable authentic records. In selecting a pure sire they should make certain that he would suit local conditions, and that he possessed strength, type, and vigor. He did not advocate any special breed, but for milking purposes recommended Jerseys, Guernseys, and Ayrshires.

The Minister of Agriculture endorsed Mr. Suter's remarks concerning the value of good feed. He had done a little dairying in the north, where they had, at times, undergone great vicissitudes so far as pastures were concerned. He remembered that in one spring the grasshoppers cleaned out the herbage. In the beginning of December the cows were producing a total of only 19lbs. of butter a week. A heavy summer rain fell, however, restored the pastures, and by the end of January production had increased to 55lbs. Last year a cow that had to be hand-fed to keep it alive had yielded 1½ pints of milk a day. Now that feed was more plentiful her daily contributions to the pail amounted to 4galls.

Mr. F. Coleman said Mr. Suter had referred to the Guernsey breed. He had been unfortunate with his stud in striking an ill-tempered sire, whose progeny took after the bull. Consequently he had disposed of the herd to a Victorian breeder, who reported that one of the heifers had turned out a phenomenal cow. He preferred

the Guernsey to the Jersey, as it had a larger frame, and was more attractive to the butcher when its milking days were done. For pedigree cattle with milking performances to their credit they must expect to pay something extra. Success in keeping milking records depended upon the interest taken in the herd and in the work by the master and the employes.

Mr. Rice (Gawler River) wanted to know what were the merits of grade Jersey-Shorthorn cross.

Mr. Suter said the period of lactation in the case of the Shorthorn was shorter, and naturally the progeny would be likely to inherit that trait rather than the better qualities of the Jersey. They could not get reliable improvement when breeding from the first cross.

Mr. Twartz (Balaklava) desired to know what breed was most suitable to meet the requirements of the farmers present.

Mr. Suter said in the Clare district he might be inclined to go in for the Ayrshire. The choice depended upon whether they were closely following dairying as a business, or were merely milking a few head in the flush of the year, and afterward selling them to the butcher. If they wanted milk and butter, the most useful breeds were the Jersey, Guernsey, and Ayrshire. One of the best crosses was a pure Jersey bull on a grade Shorthorn. This would produce a heavy-yielding deep cow close to the dual purpose type. If they wanted only flush milkers they should stick to the large-framed stock.

Mr. Bottrill (Narrung) said he always took the horns off the bull at two years of age, and found that it made them docile. He had grazed his cows on lucerne one hour in the morning, before turning them out on other pastures. Under that system he had had no complaints about taint in the cream.

Mr. Suter said he believed that bulls inclined to be cantankerous could be quietened by educating them when they were young. He strongly recommended the dehorning of milkers. With regard to taint from lucerne, in Mr. Bottrill's case sufficient time had elapsed between milking to allow the gaseous effects to pass away. He did not favor depasturing stock on lucerne in the morning, especially if it was wet and the animals were hungry. It was almost certain then to cause hoven, and perhaps result in the death of some of their best cows. The practice also diminished the longevity of the lucerne plants. He strongly advised that the lucerne should be cut two or three hours before it was fed to the cows, thus preventing any danger of it detrimentally affecting them.

## WHEAT SELECTION.

Mr. W. J. Spafford (Superintendent of Experimental Work) inaugurated the afternoon session with a comprehensive address on "Wheat Selection." The improvement of wheats by selection, he said, was by no means a new subject, yet there were a great many to be convinced of the necessity for it. Most farmers were satisfied that it was the proper thing to use good seed of good varieties of wheats, but few recognised that it should be a part of ordinary farm practice to produce first-class seed for each season's crop; or, failing that, to be prepared to pay a price above f.a.q. for all seed used. The main stumbling block to sheeting that home appeared to be that the agriculturists would not realise that producing seeds by plants was quite similar to giving birth to young animals, and that that reproduction, of itself, followed exactly the same laws as applied to animals. He felt quite certain of that, because so many farmers were very careful where they bought their ewes and rams; and were very particular what stallions they used; but when it came to the seed wheat it was quite a different tale. The sooner the fact that plants bred like animals, and were subject to the same laws, was properly appreciated, the sooner would growers of wheat realise the advantage of considering what seed they used. Imagine what would happen to our Merino flocks if they were neglected like wheat was! They would deteriorate past recognition! Professor Perkins, when in Spain (the home of the Merino) in 1910, secured photographs of Merinos hard to recognise as sheep; and those flocks had received just as good treatment as did a good deal of our wheat.

The practice of retaining a good, well-grown piece of crop, harvesting it separately, and giving it an extra cleaning, was still considered by far too many farmers to be all that was necessary in obtaining seed. That practice, of course, was better than just taking f.a.q. wheat from stack, but it did not go nearly far enough. It was about on a par with saving the ewe lambs for breeding purposes from the part of the flock in the best field, quite irrespective of what the dams or the sires were like. Then there were still some who pinned their faith to "change of seed" as the only way to produce good wheat crops. The ridiculousness of that was easily demonstrated. Professor G. W. Shaw (chemist and officer in charge of cereal stations connected with the University of California) had very thorough experimental work conducted on four stations under his charge, with a view of testing the effect of change of seed. In the experiments varieties grown on the stations were sent to parts of the State, and grown for varying periods before any seed was taken

from them and sown at their original home. The returned seed was always sown alongside of seed that had been grown continuously for some years on the station farm; and in every instance the "old" seed gave greater returns than that which had had a change of conditions. He summed up by saying that "loss always occurs by mere change of seed, except only when there is a change to a better type of wheat or more vigorous grain of the same type." At Roseworthy Agricultural College King's Early wheat had been grown continuously for the last 20 odd years, without change of seed; and the average yield of that variety for the last eight years had been 20bush.—though the last three of those had been bad grain years. Gluyas also had been grown at that institution for the last 18 years without change of seed, and a block of it last harvest yielded 26bush. to the acre. Those illustrations did not tend to show that a change of seed was necessary.

There were some people who claimed that the only way to improve plants was by cross-fertilisation; but if that were true of plants it also was true of animals, and he would like to give one local instance bearing on the point. The well-known flock of Merino sheep owned by the Messrs. Murray had been in the forefront for more than 60 years, and there had been no introduction of new blood. Did it look as though cross-fertilisation were necessary to improve forms of life? Cross-fertilisation, certainly, was one way of improving wheats; but it was an expert's job. Not many farmers were in a position to put in the enormous amount of time necessary, nor for that matter were too many of them fitted for such work. In any case, only a few men, because of its difficulties, would ever be utilising cross-fertilisation to improve wheats; but all farmers could do a little toward improving the good wheats already available, or, at least, prevent them from deteriorating. All of them could remember some really good wheats which were hardly heard of nowadays. "Because," some of them would say, "better wheats had taken their place," which was true in some cases, but not so true as they tried to make out. For instance, Marshall's No. 3 was not so good as it was some years ago, not because a new wheat had taken its place, but because it had been neglected. There had been complaints lately about Federation, and unless more men than the few who were keeping it up to the standard came into the field, it would go the way other good wheats had gone. He mentioned these two varieties because they were both wonderful wheats for Australian conditions.

Selection was very evident in all forms of life used by man. They had only to look on any of the domesticated animals or cultivated

plants, and then let their minds go back to what they had read of their "wild" forms, to realise what selection was capable of achieving. All of the types and varieties of wheats originated from a small, insignificant plant carrying only one grain. Mangels, red beet, silver beet, and sugar beet were all derived from a small plant that grew on the seashore. Cabbage, cauliflower, kohl rabi, marrow stem cabbage, originated in a small woody plant. And in the memory of man see what had happened to the sugar beet. In 1836 it took 1,800lbs. of roots to produce 100lbs. of sugar, but in 1910, only 700lbs. was needed of roots for the 100lbs. of sugar; and in some cases the beets contained as much as 20 per cent. of sugar. Now for the methods of improving wheats well within the reach of farmers: First there was the selection of the grain. This was done by a machine known as a grader, and was usually spoken of as "grading." It consisted of separating the largest and plumpest of the grains from the broken and the shrivelled ones, and the removal of most seeds of other plants. This treatment did much to improve yields when only the best grains were used for seed, and it certainly improved the plants that came under its influence; but it did practically nothing toward keeping the varieties down to one type. This grading of the seed had been proved again and again to much more than pay for itself in the increased crop. Dr. N. A. Cobb, while in the New South Wales Department of Agriculture, tested this question thoroughly for five years, and used 24 varieties of wheats.

He had summed up his results as follows:—"1. The germinating power of large seeds is greater than that of small ones of the same variety and the same harvest. 2. Under similar conditions large seeds always give higher yields of both grain and straw. 3. The percentage of large grains in wheat from large seed is always greater than from small seeds. 4. The weight per bushel of grain produced from large seed is greater than from small seed." At the Ontario Agricultural College, in Canada, the question was tested for a number of years. Plump seed of Winter Wheat averaged for six years 46.9bush. per acre, while shrivelled seed gave only 39.1 bushels; and plump seed of Spring Wheat averaged for eight years 21.7bush., against 16.7bush. for shrivelled seed. Much the same thing had happened in all countries. At Wyuna Experimental Farm, in Victoria, a "Mayer" grader was used, and the various grades obtained were sown separately. Grade 1 (large and plump seed) averaged 28bush. 6lbs. to the acre, whereas ungraded seed yielded only 25bush. 27lbs. That represented an increase of a little more than 2½bush. in favor of grading.

To "grade" wheat with a "Mayer" grader, similar to that used at Wyuna, would cost about 7d. per bushel, as follows:—A man and a boy working a "Mayer" hand grader, costing about £80, would pass through the machine about 80bush. of wheat a day, of which about 60bush. would be seed and 20bush. seconds, thirds, and broken grains. A man at 8s. and a boy at 2s. would mean 10s. as wages; depreciation at 10 per cent. per annum and (say) working 30 days a year, would absorb 5s. 4d., string, oil, &c., 8d., making a total of 16s.; loss of 1s. a bushel on seconds and thirds would involve 20s., thus making the grand total 36s., and the average cost 7d. a bushel. The increase of  $2\frac{1}{2}$ bush. at Wyuna at (say) 3s. 6d. a bushel, represented a gain of 8s. 2d. an acre over and above grading. Even if from extraordinary circumstances the cost of grading rose to 1s. a bushel, it would need only an increase of about one-third of a bushel to the acre to pay for this. Grading the seed was a profitable part of selection, but it was only a part of what was necessary.

The scheme for the improvement of wheat by selection which he wanted to put before them hinged on the same point as that of all stock breeders—the keeping of a stud. The need for a stud in connection with stock was quite evident, and it was just as essential for plants. In the working of this stud plot of wheat, following were the points on which success depended:—1. The picking of the best from the best, which was possible only by 2. Using single rows. 3. The stud plots, like stock studs, must be continuous. Picking the best was very hard to put into ordinary language, as everything rested on the natural judgment of the individual. The choosing the biggest grain was easy enough, as a sieve would do that, but when it came to quality of grain and the best plants everything depended upon the breeder. He advised them to set a standard for all the points they were looking for, and to keep as near that standard as possible. The necessity for separate rows could not be emphasized too much. Having the plants in single rows gave one a chance to get all round the plants, and so made it easy to see all strangers, and plants not of the type wanted, and also to compare the plants one with the other. It also made the removal of weeds comparatively easy. Many of them had picked barley from their wheat crops. Barley stood out very boldly from wheat, and was easily seen, but any one was lucky to be able to remove on the second or even the third trip through the crop all of the barley. How much more difficult it was to remove another variety of wheat from a standing crop could be imagined. Indeed, it was practically impossible. The selection in the stud plots must be continuous to be successful, which amounted to building up a pedigree. If wheats were selected for

a number of consecutive years, they would certainly have bred into them a certain amount of constancy of type, but this would disappear in a few seasons if selection were discontinued. Once selection was dropped, it meant making a fresh start to bring the variety to the stage it had reached before the break occurred.

For the starting of the stud plots he advised the following procedure:—First fix on one or two varieties suited to the district, and from well-grown parts of the crop of these varieties pick the best heads from the best plants. Rub the grain out of these heads at some favorable opportunity, and grade them on a sieve. For that purpose a piece of an old winnower sieve nailed to a frame was quite good enough. Count the graded grains obtained, to get an idea of the size of the plot needed, and store the grain in tins, away from mice and weevil. At seeding, leave a rectangular piece in the middle of a fallow field, so that the stud plots would have crop all round them as a protection against birds. After the bulk seeding was completed, drill superphosphate into this piece, being careful to have the hoes of the drill all level, and not staggered. This would leave the drill marks nice and distinct. Go along the first row to be planted with a rake, using the back of it as a rammer, and thus breaking lumps and making the furrow for planting a regular depth. Drop the grain of wheat into the furrow by hand, about 8 in. apart, and then rake in one bank of the furrow to cover the grain. Miss three hoe marks, and treat the fourth one from the row planted in the same manner, and so on until all the grains of a variety were sown. When treating more than one variety miss five instead of three drill marks, where the varieties were alongside one another. If this plot was horse-hoed a couple of times during its growth, besides killing weeds and improving the development of the plants, the process would prolong the growing period, and so the plots would not be ready to harvest until the bulk of the crops were off. As harvest approached it was necessary to go through the plots a number of times, and to pull up by the roots all “strangers” and plants not the type required. These could, of course, be fed to stock. Having reduced the plot to the type wanted, pick the best heads from the best plants, and treat these in exactly the same way as the original heads were, and use the grain for the same class of plots the following seeding. This means every year picking the best of the stud plots to supply the grain for next season’s stud plots. What remained in the stud plot after selecting enough for next year’s plot was harvested with the ordinary stripper, cleaned, and graded, ready to be sown on a good piece of fallow the coming seeding, to produce seed for the farm requirements.

From 150 to 200 heads would give 6,000 to 7,000 graded grains, which, if sown in rows, as indicated, would produce enough grain after being graded to sow from half an acre to three acres, according to the season. This number of grains would occupy about quarter of an acre of land when sown in every fourth hoe mark of the drill, and about 8 in. apart in the rows. The grain could be easily planted by one man in half a day, and each horse-hoeing would not take more than a couple of hours. He did not advise anybody to start with more than one or two varieties. It was easy to include others when they had gained the necessary experience. The scheme outlined was all that was required for varieties that were fixed in their characters, but to "fix" characters by that process took too long. Some varieties are always "sporting," and they would see those "throwbacks" when they used single rows. With these it was necessary to go to a good deal more trouble. Instead of just rubbing out the selected heads, clubbing the grain together, and grading it, it became necessary to keep the grains from each head separated from their neighbors, and this must be done for at least three years. He advised them to rub out each head by itself, grade the grain, and wrap it in a piece of paper or in a small envelope. At planting time, instead of going straight ahead with the rows, plant what was in one packet, miss about 3 ft. of the row, then the next packet, and so on. This would mean a lot of short rows in a row. At harvest time select only the heads from those short rows which had not "sport" in any way. Next seeding repeat this single head arrangement. If any of these short rows should "sport" at all, pull up all the plants making in that row. When the plants kept true to type for three years running they could feel nearly certain that they would always do so. All other treatment of these plots was similar to that previously indicated. With all this class of work great care was necessary. The main direction in which neglect was likely to be shown was in the cleanliness of the implements used. When drilling the super. into the block, not a seed must be in the machine which could fall on the land, and in harvesting and cleaning the grain the stripper, winnower, and grader must be absolutely free from all grains.

He had summarised his points as follows:—

1. Plants when producing seed follow the same laws of breeding as do animals.
2. Change of seed is not an improvement, let alone a necessity, unless it is for a better variety or more vigorous seed.

3. Leaving a clean piece of crop for seed and giving it an extra cleaning does not go nearly far enough towards improving your wheat.
4. Cross-fertilisation is an expert's job; it produces new varieties, but is not necessary to improve wheats.
5. Selection of plants is just as important as selection of animals.
6. Selection to be successful must be continuous.
7. First and simplest step towards improvement of wheat is "grading."
8. To get the full benefits of selection must work up a pedigree for the different varieties.
9. The simplest way to work "stud" plots is to year after year pick the best, sowing the best grains from these in single rows.
10. For varieties that "sport" the grain from each head should be kept apart from its neighbor's, in these single rows.
11. Care and cleanliness must be observed with everything connected with this work.
12. Improvement of wheats is becoming more necessary every year, and if you are not prepared to make this a part of your ordinary operations, you must be prepared to pay higher prices for seed, to those that will breed it.

Mr. Coleman said he had listened to Mr. Spafford with the greatest interest and pleasure. In him they had a thoroughly practical man, who understood the work of wheat breeding and selection in all its aspects. He was convinced that by all the farmers assiduously practising selection it would be possible in a very short period to increase the average and aggregate yields of wheat in Australia tremendously. The principal reason some of the older varieties of wheat had deteriorated was that there had been little or no selection attempted. He had been selecting regularly for a considerable time, and it might interest them to know that although this last season his crop had not averaged 7bush. to the acre, for the previous 12 years the average had been 12bush. per acre. He emphasized the importance of selecting only the best heads from the best plants.

A delegate desired to be informed whether it was possible for bees to cross-fertilise wheat plants.

Mr. Spafford replied that as the self-fertilisation took place before the glumes opened, the only way in which insects could effect cross-fertilisation was by boring into them. If that were not so it would be impossible to grow one variety alongside another without the constant danger of cross-fertilisation.

Mr. G. Jeffrey paid a warm tribute to Mr. Spafford, in whom, he considered, they had discovered another agricultural genius.

## CONSERVATION OF FODDER.

Mr. F. Phillips (Riverton) dealt with "The Conservation of Fodder." He set out by describing briefly the practice usually adopted on lower northern farms. On an establishment carrying between 12 and 15 working horses that were fed on chaff or hay chaff for 10 or 11 months in the year, a few young horses at certain times, and two or three cows, the provision generally made for them in the way of fodder, he said, was a stack of hay containing about 50 tons. When the seasons were good that procedure was sound and satisfactory, but when the crops failed, even only partially, it proved to be a very dear policy. At first when he started farming in 1905 about 30 acres were required to produce sufficient feed for his horses during the year. That was a fair slice out of 300 acres, so he determined to stack each season a certain amount of straw treated with molasses. As the seasons continued good, and he could not see many old farmers stacking straw, but always burning it and having nice clean land to plough, he began to lose sight of the advantages of having a supply of straw, and finally gave up the practice of stacking it.

To-day he was sorry. This, the first drought he had experienced, had demonstrated conclusively what a huge mistake he had made in departing from his original intentions—intentions which had been inspired by the stories he had heard regarding the effects of previous droughts. Had he persevered as he began he would undoubtedly have been in a better position now than any other farmer in the district to carry his stock through the coming season. Should the season be an average one he suggested that the farmer who required about 50 tons of hay for his working horses should stack about 45 tons handy to the chaffcutter, and put an extra 30 tons in a separate stack as a reserve. Should the man, toward the following season, see that there was a reasonable chance of obtaining an average crop, and the price be right, he could, if he felt so inclined, sell the odd 30 tons. In other words each season when he had secured his 70 or 80 tons of hay he could think of selling any surplus, but he should make certain of feed for 12 months, and a little more. Instead of burning off all the stubble a proportion at least should be stacked in the paddock. As every load was brought to the stack it should be sprinkled with a solution of molasses and water, and when the stack was complete it should be securely fenced. Some might think that the pursuance of that plan would reduce the quantity of feed left in the stubbles after harvest. To an extent it would, but they must bear in mind the important fact that by having some control over that feed it

would last considerably longer. By cutting the straw and stacking it before the horses were allowed to enter the paddock it would be much cleaner, and better results would be obtained from it. Barley and oaten straw should be cut and carted immediately after the stripping, because both were easily spoiled by rain.

Some farmers contended that straw was not of much use, and one had assured him that it killed horses, in consequence of which he advocated cutting a little more hay each year, and letting the straw go. He (Mr. Phillips), however, was convinced that if all the farmers in South Australia had built a stack of straw in each paddock cropped each year since the drought of 1902 they would now be in a much happier position than they were. (Hear, hear.) Since 1905 the price of hay had exceeded £4 a ton on three occasions, and at present it was in the neighborhood of £8 10s. Straw, he believed, was worth nearly £3 a ton. Of course he realised that it was easy to be wise after the event, but earlier in his farming experience old hands had told him that hay never would be dear again (say, £6 a ton); that superphosphate and cultivation had done away with big prices, and that droughts were a thing of the past. He was convinced now that men who talked in that strain were of little use to the State as farmers. Australia was a land of droughts and years of plenty, and he thought that if the question were approached and handled in a business-like manner it would be possible, to a large extent, to hold over stock during the dry years.

Cocky chaff was another form of feed he had seen wasted. Large heaps of it were burnt merely to get them out of the way, and because at the time there was no particular need for the fodder. Cocky chaff, if placed on high ground and well covered with straw, would keep for years. Then, when required, if mixed with bran or hay chaff it would help materially to augment the supply of fodder. He had not attempted to touch on the growing of special fodder crops, such as lucerne, rape, &c., because really it was a distinct subject, involving the question of expense to a much greater extent than the harvesting of hay, straw, and cocky chaff, as wheat was the general means of obtaining fodder for stock. Given a good supply of water, good, clean straw would enable stock that were not working to hold their own. It was scarcely necessary to emphasize the cost of feeding their working horses to-day. It would need a good crop to cover the cost of 50 tons of chaff at £8 a ton. They had learnt how to cultivate their land, and to use superphosphates so as to grow crops in average dry seasons—the present season, of course, was exceptionally dry—but they had not yet learned how to conserve fodder for their stock, so that they could hold them

during dry years without having to call heavily upon their banking accounts. So soon as they did learn that, however, the stock-carrying capacity of their farms would be increased out of all knowledge. In conclusion, he contended that every sheaf of hay saved during years of plenty would pay the careful farmer a dividend on an average, once every four years.

In the discussion which followed Mr. Rice (Gawler River) complimented Mr. Phillips upon his able treatment of the subject. It was interesting to reflect that the 1913-14 hay crop was sold in the stack at about £2 a ton, and growers then wondered whether it would not pay better to chaff it and feed it to stock. However, prices were all right to-day for those who had the fodder to sell. The tip to conserve fodder in times of plenty was well worth emphasizing.

Mr. C. E. Birks said that about 15 years ago he tried the system of threshing a portion of his crop, and placing the straw in convenient stacks. After several years, however, he came to the conclusion that the policy, on the whole, did not pay. But at the end of eight years he was compelled to acknowledge that he had been hasty in his judgment, and that the practice did pay. Every stack was used in a year when fodder was dear and herbage scarce. It opened up fresh and sweet, and the stock ate it with avidity. The dry seasons had demonstrated conclusively that it would pay to thresh fully a third of their crop, and unquestionably they ought to so treat at least a part of their crop. A small travelling machine which could be worked economically was recommended. To make the work profitable the crop handled should be one going 18bush. to the acre or over. He was satisfied that the practice would pay handsomely if carried out over a series of years.

### WATER SUPPLY ON THE FARM.

Mr. H. H. Thomas (Burra) contributed a paper on "The water supply on the farm." He said every man who got the most possible out of the land was an asset to the State. The water supply was an important factor. It helped materially in the sale of a farm, for the first question of a probable purchaser was, "What is the water supply like?" A permanent supply of good water was necessary for convenient and satisfactory working. A dam should be constructed near the homestead, and care taken to keep the water pure. Manure and other foul matter left lying about was liable to find its way into the water, and thus facilitate the breeding of harmful germs. To prevent that the dam should have a bank all round it. To ensure a permanent supply water should also, if possible, be

obtained by boring. The divining rod in capable hands was a reliable instrument in indicating the whereabouts of underground water. Boring was cheaper and quicker than well-sinking. Where there was any likelihood of drift he recommended putting down a casing. He would instal a 2in. delivery and suction pipe, and a 3½in. cylinder long stroke brass pump well down into the water. For ordinary purposes a 10ft. mill, with a 3,000-gall. storage tank, would be sufficient, but if stock were to be watered an engine (2 h.p.) would be necessary to ensure constant supplies. The self-action gear of the mill for keeping the tank full, ball and float valve on the trough to regulate filling, and the screw greasers on the mill were very convenient. He favored sprinklers for irrigating lucerne.

Mr. F. H. Kelly drew attention to the melons exhibited in the hall. He said he had grown them within eight weeks with dam water, using a set piece of piping 50ft. long, perforated every 5ft. with holes, through which the water dribbled. He had cut one melon which, after seven weeks' growth, turned the scales at 16lbs.

Mr. Winkler (Gawler River) considered that the holes would rust out and become too large. He intended to put down a 6,000gall. or 7,000gall. tank in the centre of a square chain, fill it with the aid of a windmill, and have four outlets. He proposed to grade the land and flood it as desired. He reckoned that there was more waste with the sprinklers than by flooding.

Mr. Isaacson (Undalya) supported Mr. Thomas's suggestion regarding the means of raising water. It was better to have the suction pipes larger than the distributing pipes. He had seen Mr. Kelly's little system of irrigation, and considered that a 50ft. length of pipe could be made to water over 200ft. of ground by connecting it with a hose. It was better than flooding.

Mr. Thomas, in reply to questions, said flooding had proved to be a failure in his district, whereas the use of sprinklers had been successful. In answer to Mr. Rice, he strongly advised farmers to secure the services of an expert "diviner" in the quest for underground water. With the help of an efficient "diviner" he had found water on a property on which wells had been sunk without result.

#### THE LAMB TRADE.

In a forceful address, Mr. W. S. Kelly (Riverton) discussed the position and prospects of the lamb trade. He pointed out that rainfall records which he had kept during the last six years had disclosed that dry Aprils and unfavorable autumns had been the rule. That had

been a bad thing for the lamb raisers. Following upon the slump in prices in the London market some years ago, many farmers had gone out of the business altogether.

A lot had been heard about the prospective high prices for wheat, but he was opposed to the policy of placing all one's eggs in a single basket. He had noticed that some men were putting all their available land under wheat, irrespective of whether it had been fallowed or not. The man who suggested that another bad season might be ahead of them would probably be regarded as a heretic; at the same time, it seemed to be rather absurd to do away with catch crops and the ability to feed stock during the growing season. He did not think they were altogether justified in assuming that they were going to receive record prices for their next crop of wheat. Efforts were being made in most countries to increase production, and it was sometimes wise when the majority were going one way to proceed in the opposite direction. They had been told that there was a tremendous reduction in the area that would be cropped in Europe, but the war was largely a siege war, and the women, old men, and children were available to cultivate and sow the land. There was also a prospect of the allied fleets forcing a way through the Dardanelles, and that would enable millions of quarters of Russian wheat to be exported immediately. On the other hand, indications just prior to the beginning of the war had pointed to a probable shortage in the world's supply of meat. Notwithstanding the war, the frozen and chilled meat trade had suffered very little dislocation, and was still in a flourishing state. Moreover, the war would create a greater demand and open up wider markets. People wanted meat as well as bread. Taking the British Army alone, it was estimated that 1,000 tons of meat was used daily. They did not know what effect the early cessation of the war would have, but it was certain there would not be any great fluctuation in the price of meat. Australia's market hitherto had been practically London alone, but in future he believed there would be a big trade with countries on the Continent. It was asserted that if the conflict should last another year, the live-stock of Europe would be depleted by 50 per cent. The wheat area could be increased very quickly, but it took a considerable time to breed up stock. The countries concerned would be glad to have outside sources of supply. They were justified in looking forward to good paying prices for meat, not only during the progress of but after the war as well.

The achievements of South Australian farmers were excellent in wheatgrowing, woolgrowing, and in breeding Merino sheep, but their record in connection with the lamb export trade was not particularly

happy. Although the Government experts had repeatedly directed attention to the importance of sheep on the farm, the lamb trade in South Australia was still in a weak and waddling condition. Last year the State exported only 30,000 lambs. That, however, had been mainly due to the extreme circumstances. Their actual backwardness compared with New Zealand and Victoria was apparent from the following figures for 1911-12:—South Australia, 130,000 carcasses; Victoria, 1,040,000; New Zealand, 3,300,000. As frozen lamb exporters they had done nothing in South Australia to be proud of, though the Middle North was thoroughly favorable for fat lamb production. He regarded dairying as a green country industry; that was, a country where green herbage was more or less continuous throughout the year. Those conditions prevailed in the South; but in many parts, especially in the North, they had to count upon practically six dry months. While such conditions were not favorable to cows, they did not prejudicially affect the sheep, because the lambs were raised and disposed of during the good months, and the only rams and the ewes were kept on. He suggested that intending breeders should not go into the business in a spasmodic and haphazard fashion. If they desired to make proper progress, conservation of fodder was imperatively necessary. The country was one of tricky autumns, fairly safe winters, and (excepting 1914) pretty good springs. He had always relied upon the spring for herbage to pull him through, and it had failed only once.

March, April, and May were months for which fodder provision should be made by lamb raisers. To meet that need this year he had threshed most of his cereal crops, and saved the straw. He was now carting out cocky chaff mixed with molasses and feeding it to sheep in troughs made with wire and old bags. He still had sufficient reserve to feed all his sheep for another six weeks. If that result could be achieved in a bad year, what might not be accomplished in a good season? The man who in future blew away any cocky chaff would be a fit subject for a mental expert to investigate. With oats at normal prices it would pay to feed them, together with cocky chaff, especially in dry autumns. It was a wise policy to sow peas when the seed could be obtained at an average figure. There were also possibilities in winter and spring catch crops. It was well to plan out the operations for each month of the year in advance. The matter of the rejects from the freezing depot was treated altogether too philosophically. In a normal season it should be possible to send in all the lambs in prime condition. A big percentage of rejects indicated that something was wrong in the farmer's management. Proper feeding was a highly important necessity, but it was also essen-

tial that every attention should be given to the question of breeding and selection. The day had passed when they could go into the sale-yards and buy at payable prices (up to 15s. a head) ewes suitable for breeding export lambs. In future farmers would have to breed their own ewes. He advocated the half-bred mother, because for the English market the light-colored meat was most desired. The cross-bred had better sprung ribs than the pure Merino, a better back, a sound constitution, and an ability to thrive.

Naturally they would want to secure the best quality wool possible from their half-bred. Therefore he recommended the use of the long-wool breeds, including Leicester, Romney Marsh, and Lincoln. On the half-bred ewe he favored using a black-nosed ram of the Down type. The resultant progeny would be equal to the best Canterbury product. The disadvantage of the half-bred was that it lambed rather later in the season than the Merino. Personally, however, he did not object to that, because he thought that on the whole people were inclined to time their lamb dropping far too early in the season. They invariably heard of the man who got 20s. for his early lambs, but they did not hear anything of the other early breeders who met with disappointment. It was true that the early bird caught the worm, but in this case there were too many birds after the worm. The industry would not be worth bothering about if they had to depend merely and entirely upon catching an early Adelaide market. The London market was the principal outlet for increased production, and the local breeders had as much chance of striking a good time there in December as they had in November. It was absurd to try to get lambs away in August, and thus fail to take advantage of the best fattening months in the year—September and October. Topped up lambs would sell well in any market. He was one of those who believed in weaning the lambs fairly early, and considered that that policy was essential when a man had only a certain amount of good feed available. In such circumstances the best course was to wean and place the lambs on this feed, and turn the ewes on to the hard pastures. It appeared to him to be absurd to send all their lambs to one central depot. He would like to see the lamb raisers in the Middle North co-operate in the erection and management of a freezing works nearer at hand. In New Zealand there were co-operative freezing works all over the place, and in fact almost alongside one another.

Mr. H. H. Thomas (Burra) said his district did not lend itself to the dairying business, but it certainly did to the lamb trade, and it only that one address had been given that day his attendance would have been thoroughly justified. He had proved the lamb industry to

be very profitable when conducted along right lines. Great difficulty was being experienced, and would continue to be experienced, in obtaining the class of breeding ewe that had been advocated. It meant an expenditure of £1 each. In the future the farmers would need to breed their own ewes themselves. In his district a large plain-bodied light-woolled Merino ewe was used as the mother and crossed with a Shropshire ram.

Mr. C. E. Birks strongly favored the plan of weaning the lambs fairly early. On one occasion some years ago, when he had a good crop of rape, he told a couple of lamb-buyers that he intended to wean his lambs and turn them on the fodder. Their comment was, "Well, then, don't ask us to buy your lambs." Nevertheless, he adopted the course he had indicated, and a little later offered the lambs to the same buyers. They promptly snapped them up, and were glad to get them. What was more, they gave him top rates. Ever since he had followed the plan of weaning the lambs and putting them on good feed by themselves.

Mr. Phillips saw in Mr. Kelly's address several arguments in favor of his contention that each year they must provide some reserve fodder for their stock.

Mr. W. H. Neale (Julia) congratulated Mr. Kelly upon the forcefulness of his address and its extreme commonsense character. He had tried both the Merino and the Crossbred mother, and found that the latter was the better, while the lamb which she produced matured earlier than that dropped by the Merino. It was also a better lamb in every respect. Lamb-raising had been a profitable business with him.

#### BONY GROWTHS ON HORSES' LEGS.

The principal feature of the evening session was an illustrated chat by the Government Veterinary Lecturer (Mr. F. E. Place) on 'Bony growths on the horse's leg.' The first illustration showed the bony column of the horse's leg and the individual components of joints like the knee and hock. The cause of bony growths, the lecturer said, was practically the same in all cases, though they got their names principally from the locality in which they were situated. They arose from Nature's desire to bring strengthening material—lime salts—to a weak or injured part. She was prodigal with her material. The result was an enlargement of bone where it should not be. A splint was between the knee and the fetlock, in the neighborhood of the splint bones, the remains of the horse's first and third toes. A ringbone was an enlargement affecting the joints between the pastern and small pastern bones, more especially between the latter and the footbone. A sidebone grew out from the wings of

the footbone, and was formed upon the lateral cartilage. The pulley bones at the back of the fetlock (seshamoids) also became involved in bony growth affecting the tendons which divided at the fetlock. The knee and the hock had their various small bones united, and the enlargement was called spavin, more particularly that of the hock. The treatment of all the bony growths consisted in stimulating the circulation so that Nature carried away the excessive lime salts which she had deposited. Therefore, in an old horse splints often disappeared in the course of time. A blister or friction hastened the process. In ringbone and sidebone the growths were permanent; treatment was of no avail, and their most serious aspect was depreciation in the horse's value. Their presence was due to hereditary tendencies, and every support should be given to the Government measures for preventing the use of unsound sires. The natural commonsense of the farmer would lead him to retain only sound mares.

#### THE 1916 CONFERENCE.

The venue of the 1916 conference was responsible for a lot of discussion. Mr. F. H. Kelly (Riverton) thought that in future arrangements should be made to hold the conference in districts farther apart than had been the practice in the past. He moved—"That the Advisory Board be empowered to select a suitable locality." This was seconded by Mr. Dunstan (Julia). Mr. F. Coleman (Vice-Chairman of the Board) thought it would be a good plan to have the gathering at Angaston, or, at any rate, in that district. If the matter was left to the Board he believed it would endeavor to arrange for the fixture being held in that neighborhood. Messrs. Rice and Winkel (Gawler River), following upon a suggestion by the Acting Secretary to the Board (Mr. H. J. Finnis), said no doubt arrangements could be made by their Branch to have the conference at Gawler, and they tabled an amendment that "Gawler be decided upon." Mr. Phillips (Riverton) expressed the opinion that the delegates should be empowered by their respective Branches to take definite action in the direction either of inviting the conference to meet in their own particular township, or of voting for it to assemble at some other place. Eventually the motion was declared carried.

#### LIVE STOCK QUESTIONS.

During the course of the "Free Parliament" several questions were addressed to Mr. Place and Mr. Spafford. The former was asked whether molasses in the drinking water was as good for stock as when given in the feed. He replied that a horse, when thirsty, would undoubtedly prefer fresh, clean water to sweetened water.

The digestion of the molasses was certainly performed better when it was mixed with the food, and he believed that the animal derived greater benefit from it in that way. Another inquirer desired to know if there was any explanation for the fact that those of his horses in the best condition were those that drank the most water. All were feeding on the stubbles. Mr. Place, in reply, said he thought the state of the best-conditioned horses was really due to the fact that they drank more than the others. It was not because they were in good condition that they drank more. It had to be remembered that about 60 per cent. of the flesh of the animal consisted of water, and it was a recognised fact that the horse which drank more than eight gallons of water a day would thrive much better than the one that consumed only six gallons. Generally an ordinary working horse drank between eight and 12 gallons, but he had noticed, in the Brown's Well country, that some of the horses took as much as 20 gallons a day. The third question put to Mr. Place was, "Is there any cure for lockjaw?" Having described the complaint and its effects, Mr. Place replied that if left alone Nature would cure about 70 per cent. of the cases. Epsom salts were a very useful assistant, especially if the horse could get at plenty of easily digested food, including bran and pollard. The fourth and final question was, "Why does a foal, which is fat, eat its mother's dung?" For the reason, Mr. Place explained, that no doubt it was suffering from worms, which induced a depraved appetite, and a liking for the salty ammonia flavor of dung. He advised scouring the foal out with castor oil (a wineglassful to a teacupful) and giving it a lump of rocksalt to play with.

### PICKLING WHEAT.

Mr. Spafford, in response to an inquiry, said, with isolated exceptions, even good samples of some wheats which had deteriorated could not now produce the crops which had been obtained from the same varieties years ago. One of the exceptions was Bluey. A delegate wanted to know why good samples of wheat raised on red land weighed heavier than similar samples grown on black ground? Mr. Spafford explained that this was usually the case, because the black ground, being rich in organic matter, produced rank growth full of sap, with the result that at the first burst of heat the grain became pinched. Relative to pickling with bluestone Mr. Spafford considered that the usual strength, 1½ lbs. in 10 gallons of water (1½ per cent.) was a little dangerous. He favored using 1 per cent. solution and pickling on the floor. When more than that strength was employed subsequent treatment with lime water or salt water was ad-

visible, as it counteracted the corrosive effect of the bluestone. Pickled wheat which was not to be used until some time after having been treated should be properly dried before it was placed in the bags, which, by-the-way, should previously have been thoroughly soaked in a solution of bluestone, so as to destroy any smut spores, and dried.

#### THANKS.

At the close of the conference Mr. R. H. Cooper moved, and Dr. Glynn seconded a hearty vote of thanks to the officers of the department and the visiting delegates, especially those who had contributed papers. This was carried with acclamation, and acknowledged by Mr. Coleman. At the instance of Mr. Rice the Riverton branch was warmly thanked for its hospitality and the completeness of the arrangements for the conference. Appreciation of the compliment was voiced by the Secretary (Mr. E. A. Gray), who deserved a generous meed of praise for the part which he played.

#### OVERSEA MARKET FOR EGGS.

Reporting to the Minister of Agriculture under date London, February 5th, the Trade Commissioner writes:—"New Zealand has just landed a large shipment of eggs in the shell, and I understand they are now available for inspection in Tooley Street, and I intend, if possible, to avail myself of the opportunity of going through them one day this week. The arrival of this shipment (which, I understand, has carried very well) is particularly opportune, and should meet an excellent market. Practically the whole of the supplies from the Continent, which used to find a ready market in England, have been stopped, with the exception of spasmodic shipments from Russia, and as the Continental export business was worth £8,250,000 a year (this amount being the value of the eggs imported annually by England from the Continent), it will be seen that the prospects for the future of the egg industry must be particularly good. Not only has the supply from the Continent been stopped for the present, but it is almost certain that in very many districts the breeding stocks of the different countries have been destroyed. I am aware that the prices offering in Australia are particularly tempting, but am strongly of the opinion that there will be an all-round increase, not only in the eggs in shell, but pulp business, from now on, and I intend getting full particulars together of the prospects and prices of the two methods of packing, and will forward further details later."

## THE WHEAT MARKET.

---

| Date. |    | LONDON (Previous Day).                                      |
|-------|----|-------------------------------------------------------------|
| March | 6  | Very weak, 9d. to 1s. lower.                                |
|       | 8  | —                                                           |
|       | 9  | Firm, rather dearer; Liverpool steadily held, not active.   |
|       | 10 | Steady, no quotation; Liverpool firm, held for higher.      |
|       | 11 | Steady but quiet.                                           |
|       | 12 | Dull and neglected.                                         |
|       | 13 | Dull and neglected.                                         |
|       | 15 | —                                                           |
|       | 16 | Firm; Liverpool unchanged.                                  |
|       | 17 | Firm, held for 6d. advance; Liverpool held for 1s. advance. |
|       | 18 | Firm, quiet.                                                |
|       | 19 | Dull, easier tendency; Liverpool very dull; lower to sell.  |
|       | 20 | Quiet; Liverpool dull and lower.                            |
|       | 22 | —                                                           |
|       | 23 | Steady, quiet; Liverpool quiet.                             |
|       | 24 | Dull, easier tendency.                                      |
|       | 25 | Slightly firmer; Liverpool dull.                            |
|       | 26 | Dull.                                                       |
|       | 27 | Dull, offered lower.                                        |
|       | 29 | —                                                           |
|       | 30 | Very dull, and lower to sell.                               |
|       | 31 | Quiet.                                                      |
| April | 1  | Firm, rather dearer.                                        |
|       | 2  | —                                                           |
|       | 3  | —                                                           |
|       | 5  | —                                                           |

The price of wheat in South Australia is still quoted at 7s. 3d. per bushel for ordinary f.a.q. on trucks, Ports Adelaide, Pirie, and Wallaroo. In Victoria for locally grown small lots the rate on April 5th was 8s. to 8s. 1d. on trucks, Williamstown, but for Argentine wheat to arrive the Government quoted 7s. 8d. per bushel to millers who undertook not to advance flour beyond £17 per ton. The prices officially fixed in New South Wales and Western Australia, viz. 5s. and 7s. 4d. per bushel respectively, remained unchanged.

## DAIRY AND FARM PRODUCE MARKETS.

A. W. Sandford & Co., Limited, report on April 1st:—

**BUTTER.**—During March rain was practically totally absent, and this was especially detrimental to dairying. Business and demand, however, continue good. "Alfa" is now selling at 1s. 5½d. per lb.; "Primus," 1s. 4½d.; choice separators and dairies, 1s. 2d. to 1s. 3d.; well-conditioned store and collectors', 1s. to 1s. 1d. per lb.

**EGG** values advanced substantially during March, and demand was keen at closing rates, which represent a big improvement over prices of a month ago. Present quotations are 1s. 6½d. per dozen for hen; duck, 1s. 7½d.

**CHEESE.**—All parcels were able to secure advanced prices, and as interstate markets have substantially hardened, rates here are likely to keep firm in sympathy. Quotations:—9d. to 9½d. per lb. for large to loaf.

**BACON.**—Curers continue to have a difficult task in coping with anything like requirements for their trade, the live market being very short of quality pigs. Best factory cured sides are selling at 10½d. to 11½d. per lb.; hams, 11d. to 1s. per lb.

**HONEY.**—Inquiry continues good for this line, both local and export, and in consequence of the shorter production previously mentioned, prices have further enhanced. Prime clear extracted is selling at 3½d. to 4d. per lb.; beeswax, 1s. 4d.

**ALMONDS.**—Although parcels continue to arrive, brisk demand has kept stocks from accumulating, and values ruled a little higher. Brandis are selling at 8½d.; mixed softshells, 7½d.; hardshells, 4d.; kernels, 1s. 6d. to 1s. 7d. per lb.

**LIVE POULTRY.**—The month of March was, like its predecessor, characterised by considerable quantities of birds coming forward from all parts, and the last week comprised Easter sales, when heavy catalogues were submitted. With brisk competition for quality, poorer grades met with a more dragging sale. Good table roosters brought 3s. 6d. to 4s. each; nice-conditioned cockerels, 2s. 6d. to 3s.; plump hens, 1s. 4d. to 2s.; small and light, 1s. to 1s. 3d.; ducks, 1s. 6d. to 2s. 6d. (ducklings and light birds lower); geese, 2s. 9d. to 3s. 6d.; pigeons, 5d.; turkeys, from 7d. to 9d. per lb. live weight for fair to good; fattening sorts, 5½d. to 6½d. per lb.

**POTATOES AND ONIONS.**—Moderate supplies of potatoes have come to hand from the Millicent district, but the Adelaide market has been mainly supported by importations from Victoria, and prices have fluctuated in sympathy with the Melbourne market. Onions are offering freely from Mount Gambier, but the samples generally are small, and consequently buyers have displayed a preference for the larger samples obtainable in Victoria. Present quotations—Potatoes, £6 15s. to £7 5s. per ton of 2,240lbs. on truck Mile End or Port Adelaide; onions, £6 to £7 per ton of 2,240lbs. on truck Mile End or Port Adelaide.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of March, 1915, also the average precipitation to the end of March, and the average annual rainfall.

| Station.                   | For March, 1915. | To end March, 1915. | Average to end March. | Average Annual Rainfall | Station.               | For March, 1915. | To end March, 1915. | Average to end March. | Average Annual Rainfall |
|----------------------------|------------------|---------------------|-----------------------|-------------------------|------------------------|------------------|---------------------|-----------------------|-------------------------|
| FAR NORTH AND UPPER NORTH. |                  |                     |                       |                         | LOWER NORTH—continued. |                  |                     |                       |                         |
| Oodnadatta .....           | —                | 0.26                | 1.83                  | 4.76                    | Gulnare .....          | 0.12             | 0.81                | 2.12                  | 19.74                   |
| Tarcoola .....             | —                | 0.57                | 1.35                  | 7.58                    | Bundaleer W. Wks. .... | 0.05             | 0.72                | 2.02                  | 17.29                   |
| Hergott .....              | —                | 0.14                | 1.47                  | 6.04                    | Yacka .....            | 0.05             | 0.62                | 1.77                  | 15.27                   |
| Farina .....               | —                | 0.32                | 1.78                  | 6.70                    | Koolunga .....         | 0.16             | 0.44                | 1.99                  | 15.94                   |
| Leigh's Creek .....        | —                | 0.21                | 1.96                  | 8.66                    | Snowtown .....         | 0.26             | 0.68                | 1.85                  | 15.70                   |
| Beltana .....              | —                | 0.52                | 2.28                  | 9.22                    | Brinkworth .....       | 0.14             | 0.44                | 1.94                  | 15.48                   |
| Blinman .....              | —                | 0.62                | 2.77                  | 12.85                   | Blyth .....            | 0.52             | 0.81                | 2.01                  | 16.34                   |
| Hookina .....              | —                | 0.88                | —                     | —                       | Clare .....            | 0.25             | 0.90                | 2.77                  | 24.30                   |
| Hawker .....               | —                | 0.78                | 1.65                  | 12.22                   | Mintaro Central .....  | 0.23             | 1.01                | 2.29                  | 21.99                   |

\* No report received during the month of March.

† Formal report only received.

‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

April 14th, and May 12th, 1915.

**NOTE.**

Owing to the space that has been devoted to the Reports of Conferences it has been found necessary to omit the publication of a number of Reports of Meetings of the Branches of the Bureau. These will be published in a later issue.—Ed.

**THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.**

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

**REPORTS OF BUREAU MEETINGS.**

Edited by H. J. FINNIS.

**UPPER-NORTH DISTRICT.**

(PETERSBURG AND NORTHWARD.)

MORCHARD (Average annual rainfall, 11in. to 12in.).

February 27th.

**DAIRYING.**—An interesting paper on dairying was contributed by Mr. R. Jasper, who favored the Jersey and Shorthorn as good milking cows. The bull should have a heavy milking ancestry on both sides. The heifers should be carefully tested, the less profitable ones being disposed of. In the discussion which followed Mr. B. S. McCallum considered that on a small farm cows were very profitable, but that it was essential to provide feed for them. Mr. J. W. Richstien had found that nux vomica and bone meal was a good cure for dry bibe. A further discussion followed on the prevention and cure of sand in horses.

WILMINGTON (Average annual rainfall, 18.26in.).

February 3rd.—Present: 10 members.

**WHEAT CLEANING.**—A short paper was contributed by Mr. H. Schieler. He considered that turning the winnower by hand was very unsatisfactory, as an even pace was not maintained, and consequently a certain amount of grain was wasted, and the sample was not as good as it might be. He favored a small engine, such as was used for driving the pump, &c., to do this work. One hundred and fifty to 200 bags of wheat per day could be cleaned, and the cost of running the machine would only be about 1s. 6d. per diem.

**QUORN, February 27th.**—Mr. Britza reported on his trip past Blood's Creek, 40 miles from Oodnadatta. He mentioned that good, well-timbered grazing country was to be found there, and if the water from Hamilton's Bore were used for irrigation purposes, the land would grow almost anything.

**TARCOWIE, December 30.**—Mr. A. Shrowder contributed a paper on the subject of "Afforestation."

**WARCOWIE, January 26th.**—Mr. A. Bairstow contributed a paper. He deplored the fact that South Australian wheat had lost its reputation for quality; which he attributed to carelessness in cleaning the sample. Members discussed the advisability of co-operatively purchasing a bull for use in this district.

**MIDDLE-NORTH DISTRICT.****(PETERSBURG TO FARRELL'S FLAT.)**

LEIGHTON (Average annual rainfall, 16in. to 17in.).

February 6th.—Present: 11 members.

**FARM MANAGEMENT.**—A short paper under this heading was read by Mr. W. H. Lloyd. He pointed out that the advancement of any farm depended on the management. Economy should be practised. The farmer who worked hard and cultivated a large portion of his farm in a haphazard way reaped no more wheat than his neighbor, who only put a small acreage under crop, but did it in a thorough manner. It had been proved that well worked fallow land repaid the farmer. Enough fodder should always be conserved, if possible, to tide over at least two years. It was also advisable to have small paddocks for growing green feed, such as barley, lucerne, or sorghum to feed stock when natural grasses were very scarce. A few side lines such as the cows, poultry, sheep, or even a fruit and vegetable garden would increase the producers' income. It was advisable to have a forge on the farm for effecting repairs, &c., and also an outfit for repairing harness. Before entering upon any undertaking the farmer should carefully consider the cost and likely benefit that would accrue, &c. A discussion followed, Messrs. A. E. McWaters, R. Fairchild, J. McDonald, H. G. Oates, and T. P. Goodridge (Chairman) taking part.

MUNDOORA (Average annual rainfall, 14.11in.).

March 1st.

**FEEDING OF LIVESTOCK.**—A paper dealing with this problem was read by Mr. I. Clothier. He said that in order to save expenditure during the next few months the best plan to adopt was to mix equal quantities of hay and cocky chaff or chaffed straw. If raked straw were used he would not mix more than one-third straw chaff, with the rest hay chaff, on account of the large amount of indigestible matter in raked straw. Young horses not being worked would have to depend on what they could find in addition to a little straw. He advised drilling a few bags of barley or early wheat at once for green feed.

**MUNDOORA.**—The majority of members stated that they had reaped from two to four bushels per acre, whilst others had only reaped sufficient for seed requirements. Mr. C. H. Button mentioned that he had had best results from a crop sown on sandy land, which last year had drifted bare, and had been sown early. It was generally considered that Gluyas had given the best results this season, especially where sown on light soils.

**LAURA, January 29.**—A paper dealing with bare fallow versus the three years system was contributed by Mr. H. R. Lines.

**LOWER-NORTH DISTRICT.****(ADELAIDE TO FARRELL'S FLAT.)**

ANGASTON (Average annual rainfall, 22.25in.).

February 5th.—Present: 15 members and three visitors.

**EXPERIMENTS.**—Wheat variety tests conducted on behalf of the Branch were reported as having failed on account of the season. Mr. Thorn had secured best results with the Comeback. Mr. S. O. Smith, who tested the effect of manurial dressings on orchard lands, had found that except where a constant supply of water was available to the trees, no results were noticeable. Mr. Matthews had effected the destruction of American blight by spraying the trees with red oil. Mr. Patching, reporting on the result of tests with summer manuring stated that the manured plots gave a third more in the yield than the untreated portions. When drilling, he used a small quantity of bonedust on one plot, and this growth maintained its greenness for fully a week longer than the other, but in growth it was four to five inches shorter. The Spraying Committee reported that the

season did not allow of a fair test. Mr. Hurn had used two gallons of the prepared oil to 75galls. of water, and sprayed peach trees after the leaves had developed. He had been successful in removing black aphid and the leaves were not affected. Mr. Wishart reported that Mr. Plush had, in pruning apricot and peach trees, left leaders their full length after the Sage system, the object being to secure a fruit of good quality and quantity. But the setting did not allow of proof of the experiment. In his own garden he had also tried this system. He had a wonderful setting of blossom, but the frost had destroyed the chance of the crop setting. Mr. Player stated that he had left big laterals on apricot trees. These bore fruit, but he could see no difference in either the quality or quantity when compared with trees not so treated. He only brought down the leader to the first little lateral. He intended to continue with the system.

#### BLYTH (Average annual rainfall, 16.46in.).

January 16th.—Present: eight members.

A manurial test was carried out by Mr. McEwin, under the auspices of the above Branch, the results of which are shown hereunder:—

| Plot.   | Super. per Acre. | Yield per Acre. |
|---------|------------------|-----------------|
| 1 ..... | 75lbs. 36/38     | 2bush. 7lbs.    |
| 2 ..... | 100lbs. 36/38    | 3bush. 35lbs.   |
| 3 ..... | 125lbs. 36/38    | 4bush. 2lbs.    |
| 4 ..... | 75lbs. 45        | 3bush. 45lbs.   |

Variety test carried out by Mr. M. Williams—

| Plot.   | Variety.   | Yield per Acre. |
|---------|------------|-----------------|
| 1 ..... | Bayah      | 7bush. 9lbs.    |
| 2 ..... | Federation | 6bush. 12lbs.   |

Owing to the extremely dry season the results were not very satisfactory, two plots being total failures.

#### GAWLER RIVER (Average annual rainfall, 17in. to 18in.).

February 22nd.

THE COW.—In dealing with this subject Mr. P. T. Hill said it was advisable for the farmer to keep to pure-bred cows. On farms where natural grasses, clover, &c., were abundant, the heavy breeds were frequently favored, but where at times the feed was scarce, the Channel Islands breeds were generally favored. "Whatever breed or breeds may be chosen the management of the milkers should be the same. The yards, to be ideal, should slope downwards from the head of the bails with an even grade that drainage may be easy and complete, and on no account should mud, refuse, manure, or water be allowed to litter and disfigure the yards. A good slope being given and a suitable floor, either of solid soil or asphalt, little labor is required to keep it in the best sanitary condition. The bails should be covered, but well ventilated. Loose straw thrown on rough timber—thick, rainproof, and wired down—forms a good roof, cool in summer and warm in winter, and preferable to palings or iron. The home paddock should be sheltered by belts of trees that stock may take refuge from wind or rain driven from any point of the compass. Wind breaks may be easily formed of pepper trees, the Port Lincoln wattle, or any other kind with thick foliage and rapid growth. For more complete shade large trees of the eucalyptus family may be easily raised where Nature has not already made that provision. It is good management to rug the animals, for about three months during winter, which results in more milk being given and less food required to keep the cows in good condition. Cows do best when treated with gentleness, and a change of milkers is objectionable; they should never be flurried, hurried, or driven in haste. A cattle dog, unless very well trained, is a mistake. Let food sufficient to last during the milking period be found in the bin, consisting of newly-cut lucerne, or chaff and bran newly mixed. If they always find their allowance awaiting them, there is but little driving necessary, for cows always find a change of food to their liking. The little herd can be taught, when the time for milking is fixed and unaltered, to come home when called, if no fences bar the way. It is one of the prettiest sights of the well-ordered farm to see the herd in line quietly following their leader on the homeward track. A lively and profitable discussion followed, and opinions differed considerably as to the best breeds to rear for dairying purposes, some contending the good crosses were more vigorous and harder than pure breeds."

**JULIA** (Average annual rainfall, 18in. to 19in.).

February 27th.—Present: 11 members and three visitors.

**SHEEPDIPPING.**—Mr. W. Hall read a paper on this subject in which he said that farmers lost fully a penny a lb. on wool badly infected with tick. In addition ewes affected in that way could not bring their lambs to maturity as quickly as they should; £5 would cover the expense of putting down a dip and draining pen. The dip should be constructed long and narrow enough to prevent the sheep turning round. The depth should be sufficient to enable them to swim the distance in the minute required to saturate the wool with the fluid.

**RIVERTON** (Average annual rainfall, 20.48in.).

September 21st.—Present: 17 members and two visitors.

**SUMMER v. WINTER FALLOWING.**—A debate on this topic took place between Messrs. G. Arthur and J. G. Kelly, jun. Mr. Arthur said that summer fallow was done mostly in black land during the months of February and March before seeding. It was most essential in dry years and was most easily worked when the land was cropped alternate years. In the latter case, it was best to burn the straw, as it left black ground too open to the sun's heat. With the three years' system it was best to plough the straw in, after a rain if possible. Early fallowing allowed weeds to germinate more quickly, and so gave a thicker crop of feed, but should be destroyed with the cultivator after seeding. Summer fallowing enabled a farmer to increase his fallowed area with little extra cost, and conserved more moisture in the land than winter fallowing. Mr. Kelly, jun., said that with winter fallowing the early rains were caught which were so essential to good farming. Early fallowing should be commenced as soon after seeding as possible, and finished by the end of August. Summer fallowing was useless when the land was cropped every three years, as it became very hard owing to the tramping of stock on it, and the undergrowth of weeds and straw held the ground together, and the strain on the horses and machines was very great. A good discussion followed.

**RIVERTON** (Average annual rainfall, 20.48in.).

March 2nd.—Present: 20 members.

The Hon. W. Hannaford, M.L.C., in reply to a question, did not favor sowing fallow land early, but he, personally, intended to sow his stubble land early next month, commencing with barley, and later on earlier wheats. Mr. W. B. Davis advised when sowing stubble land to drill the manure in first, and then sow the grain broadcast, as in that way he contended more ground could be covered. In reply to a question with reference to the sowing of rape with manure, Mr. H. C. Thomas said that his experience proved that rape sown with manure always gave a bad germination, and resulted in only a few plants to the acre. He strongly advocated planting rape without manure, if good results were desired, as manure clung to the rape seed, which was of an oily nature, and so killed the germ. He generally sowed about 6lbs. to the acre. Mr. W. H. A. Davis advised sowing barley, rye, and oats for fodder. Lucerne germinated splendidly if mixed with sifted sand and sown through the wheat feeders.

**BLYTH**, February 13th.—**STABLE MANURE.**—A paper on this subject was read by Mr. McEwin.

**MALLALA**, February 1st.—An interesting discussion on stock diseases took place.

## YORKE PENINSULA DISTRICT.

(TO BUTE.)

**ARTHURTON** (Average annual rainfall, 16in. to 17in.).

February 18th.—Present: 11 members.

**GREEN FEED.**—Mr. W. R. Stephenson said that seeds put in at the present time were not likely to malt, as there was no moisture in the ground. On

the other hand, if not sown until after good rains, the feed was likely to come up stronger and be more permanent. It was essential, owing to the scarcity of fodder, to do all possible to get early feed. Past experience had proved the value of having 2 acres or 3 acres of barley ready for feeding during fallowing.

**STUBBLE LAND.**—Proceeding to the question as to the advisability of drilling for wheat this year the stubble land, which had just produced only a light crop, the same gentleman said that such land would not take much working, as it was loose and well pulverised, and a good seedbed was thus provided. Under present conditions it was imperative that as much land as possible be put under crop this year. A discussion of these questions followed.

**MAITLAND, March 6th.**—In reply to a question as to which was the best method to protect heaps of cocky chaff from the elements Mr. A. Darling advised covering the heap with straw about 18in. thick, commencing to work from the ground. The Hon. Secretary added that it would be better to first build an enclosure of wire netting of 2in. mesh, some 6ft. high and 15ft. wide, and then build the straw cover on supports to allow the passage of air between the chaff and the straw. Messrs. Bawden and Bentley favored an iron shed, and agreed that the passage of air was essential.

**YORKETOWN, January 9th.**—In reply to a question as to the best way to castrate rams over five months old, it was stated that the most important thing to be observed was cleanliness. Condyl's fluid should be plentifully used.

## WESTERN DISTRICT.

**KOPPIO** (Average annual rainfall, 22.40in.).

January 28th.—Present: 11 members and one visitor.

**NOTES ON THE SEASON, 1914.**—Mr. W. R. Richardson read a paper on this topic, in which he said that although the total rainfall of 1914 would have been quite adequate for the production of cereals in many districts it was quite insufficient in our own, under the system commonly adopted. In the future he advised farmers not to put in a greater area than could be worked thoroughly, a moderate area carefully put in would pay better than a larger area carelessly treated. It was useless to expect a crop in a dry season from any land but well worked fallow. Late sowing was useless if the growing season was short. Quick growing and early maturing wheats only should be sown, as these gave better results both for grain and hay. He emphasized the advisability of having a reserve of fodder—straw and cocky chaff—for a season such as this. In the discussion which followed Mr. G. B. Gardner did not favor sowing early wheat in a normal season, while Mr. Newell advised sowing a fair proportion of late and early wheat, but thought it profitable to sow more barley and oats on account of the value of the stubble for the stock. Members had had excellent results from feeding non-working horses on cocky chaff and molasses. Mr. G. B. Gardner gave the result of experiments, and said that he had cropped a paddock continuously for eight years, and had good returns each year. He then left it out for two years, and found the succeeding crops not so good. The following manurial tests were made by Mr. J. Newell on stubble land ploughed in March, cultivated on May 3rd, drilled with 1bush. per plot of Calcutta Cape oats on May 14th, and harrowed after the drill:—

(1) *With 36/38 Mineral Super., at £4 10s. per ton.*

| Plot.   | Super. | Hay. | Gross Value. | Cost Seed and Super. |
|---------|--------|------|--------------|----------------------|
|         | lbs.   | lbs. | s. d.        | s. d.                |
| 1 ..... | 112    | 288  | 9 0          | 6 6                  |
| 2 ..... | 224    | 208  | 6 6          | 11 0                 |
| 3 ..... | 336    | 256  | 8 0          | 15 6                 |

| Plot.   | (2) With Super., at £4 per ton. |      | Gross Value. | Cost Seed and Super |
|---------|---------------------------------|------|--------------|---------------------|
|         | Super.                          | Hay. |              |                     |
|         | lbs.                            | lbs. | s. d.        | s. d.               |
| 1 ..... | 112                             | 240  | 7 6          | 6 0                 |
| 2 ..... | 224                             | 108  | 3 6          | 10 0                |
| 3 ..... | 336                             | 116  | 3 8          | 14 0                |

The above calculations were on a basis of 2s. per bushel for seed and 70s. per ton for hay.

#### MITCHELL.

November 28th.—Present: 10 members and three visitors.

**TREATMENT OF MARES.**—A paper on this subject was read by Mr. W. J. Timble, in which he said that to tell when a mare was in foal it was necessary after the first service of the horse to examine the bearing. If conception had not taken place it would be a fresh, bright, florid color, and of a moist appearance, with a clear drop appearing at the lower part, which, if touched, would tend to extend. If, however, conception had been effected, it would be found to be dry and of a dirty brown rust color, and a dark brown drop would replace the clear drop. With these appearances pregnancy could be regarded as certain. Forty-four weeks was the average period of gestation with a mare, but this might be either lessened or exceeded by a few weeks. After the service the mare should not be put immediately to quick work, or strained in any way or she was apt to abort. She should always be kept away from string-proud or badly castrated geldings, as they were apt to worry her into casting the conception, or later on slinking her foal. Moderate work would be beneficial rather than injurious, and this might be continued until the time of foaling. Special care should be taken to guard her from being kicked, thrown, or in any way strained. The mare after foaling would be in season again sometime within the following 30 days, when she should again go to the horse is she were to be bred at all. The ninth day after foaling would generally be found the right time, but whenever indications of heat were noticed the matter should not be delayed. The days of trial were the ninth, the seventh following, then the fifth and seventh, which should be sufficient to prove her. One or two days before foaling a sticky substance would be found protruding from each teat, somewhat resembling wax. The mare should then be removed to a small paddock near the house by herself and a careful watch kept over her, as this was a certain indication of a near delivery. Previous to this sign a furrow-like fold would be seen on each side of the spinal column, and the bag would generally be found to have increased in size. These signs showed that delivery was not far remote, but could not be relied on to denote the day. When about half the time of pregnancy was passed the mare required better feeding and kinder handling than previously, as at this time the rapid growth of the foal made a constant and severe drain upon her system. Lack of care might cause abortion, and if a mare once cast her foal she was apt to do so at a corresponding period of pregnancy afterwards, particularly if a like provocation occurred. Among the other causes of abortion might be mentioned, allowing a mare to see and smell, but not partake of, food to which she has become accustomed and of which she was fond, seeing another pregnant mare cast her foal, and smelling blood or freshly slaughtered meat. Should the mare sink because of a hurt or acute attack of disease, she was not apt to fall into the habit of abortion provided care was taken to guard her against exciting causes at a corresponding period of her next pregnancy. If symptoms of casting were noticed in time it might be prevented by burning feathers in a pan of coals and obliging her to inhale the smoke.

**ELBOW HILL, February 27th.**—In answer to a question as to whether it was any use ploughing when the soil was dry, Mr. G. F. Wake stated that land worked now would not require so much working after the rain as land not so treated. Mr. A. Wake advised at once harrowing all land intended for cropping, thus securing a thorough germination of the weeds when the rain fell.

**KOONIBBA, February 23rd.**—A paper on the "Farm Implements," written by Mr. E. E. Lutz, was read by Mr. J. Foggo. An interesting discussion on the

plough followed. Mr. E. Gersch favored a high-bodied plough with low wheels as being better for clearing stumps. Mr. H. Schroeder differed, and advocated a high-wheeled plough as being easier running, lighter on the horses, and not so rough on the implement when passing over stumps as low wheels. Several other members contributed to the discussion.

## EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

### BERRI.

January 30th.—Present: 20 members and three visitors.

CO-OPERATION.—Mr. S. Phillips contributed a lengthy paper on this subject. He was confident that the fruitgrowers of this district would not reap the full benefit of their labors until they co-operated in the marketing, &c., of their produce. Packing, grading, preserving, &c., could be done much more satisfactorily by a co-operative union, and consequently better prices could be obtained. By trading with large parcels of merchandise freights, &c., would be reduced. Manures, implements, packing cases, &c., could be obtained more cheaply by a union than by the individual. Another distinct advantage was that the union was able to advertise the produce and bring it prominently before the world's markets. Members discussed the paper, and the hope was expressed that the growers of this district would soon unite to their mutual advantage and benefit.

### BOOKPURNONG EAST.

January 30th.—Present: 13 members.

DESTRUCTION OF MALLEE SHOOTS.—Mr. E. F. Mayfield read a paper on this subject, in which he stated that in 1910 he had 100 acres of shoots cut down each month from August until February, 1911, about 700 acres in all. This land was then cropped. There were about 10 shoots to the acre on that cut in August, while there were between 100 and 120 to the acre on that cut in January and February. The difference in the grain yield was also very marked, that on which shoots were cut in August yielding 10bush. per acre, while the later cut only yielded 5bush. per acre. He had found that the best time for fire harrowing was between the middle of February and the middle of March, when from 70 per cent. to 80 per cent. of the shoots would be destroyed. The plough was a great factor in getting rid of stumps, particularly when set to a depth of about 4in., and with plenty of draught. He advised farmers to cut their scrub in August, and burn as soon as the law allowed and then plough the ground as soon as possible. It was well to burn the stubble at the earliest moment, and to cut any shoots that had not been scorched and plough again before seeding.

CLANFIELD (Average annual rainfall 16in. to 17in.).

December 5th.—Present: 11 members and two visitors.

AVERAGE COST PER ACRE OF WHEAT PRODUCTION.—Mr. Wilkins read a paper dealing with this question, and said that his calculations would refer to a farm of about 1,200 acres, with about two-thirds heavy land and one-third sandy loam, and sufficiently cleared to allow the use of the share plough. Until the shoots were killed he advised putting 600 acres under crop, 400 acres fallow, and using the remainder for grazing. Fallowing should be commenced as soon after seeding as convenient. He thought it best when half the fallowing was completed to harrow that portion before completing the fallowing, and so give the weeds a chance to grow. The harrow should always be used when the land was in a damp state. With the appearance of the weeds cultivation should be commenced, preferably when the land was damp underneath, but in dry weather. These operations should be completed early in the year. Loose stumps having been gathered into heaps and burnt, the preparation of the 200 acres of stubble land might be proceeded with. Should a good burn have been obtained, it was best to work the land lightly with a cultivator after the first rain, and work again ahead of the

drill. He advised harrowing heavy land, but not sand ridges, after the drill. After the wheat was well up, he considered it good to roll the land, and so press all small stumps well in, when they would be destroyed by the white ants. Referring to harvesting, he preferred using damp-weather strippers, and as the land became clearer one harvester on the farm would be advantageous. After giving detailed figures, he came to the conclusion that the average cost of production would be £1 14s. per acre. A discussion followed.

#### CLAYPAN BORE (Average annual rainfall, 16in. to 17in.).

February 17th.—Present: seven members.

**SORE SHOULDERS.**—This subject was dealt with in a lengthy paper by Mr. C. Dunstone. Horse owners, he said, should endeavor to prevent sore shoulders right at the outset, when breaking in the young animals. In the majority of cases the primary cause was a bad fitting collar; it being as harmful to have a collar too large as too small. If the colt were fat the collar should be just a little tight when first fitted, and he should only be worked half a day at a stretch until the shoulders were hardened. He deprecated the practice of throwing cold water on the shoulders at night to assist the hardening process, as this often caused a collar ring of hard skin to form, which afterwards peeled off, and left the shoulders tender. It was important also to see that the hames fitted well. If the collar and hames fitted well, and yet the sores appeared, one generally found the cause of the trouble in the collar lining. He preferred horsehair padding and good saddle cloth lining. A horse fresh from the paddock and in good condition was very apt to develop little boils before it has been working a week. These broke into sores if neglected, but if attended to promptly this could be prevented. When a sore was detected the wound should be kept very clean. A small quantity of dark paste or lubricant should be placed on it, and the collar then put on. The animal should then be worked for an hour or two. On taking the collar off a dark mark would be found on the lining exactly where it pressed on the sore. With a bag needle or saddler's awl the stuffing of the collar should be worked away from this spot towards the front of the collar, taking care that it was evenly distributed or another sore might be the result. The hollow thus formed should be somewhat longer than the wound, to ensure all pressure being taken off it. If an animal's shoulder received a jar it should be bathed with some antiseptic in hot water. It would not be necessary to spell the horse. Scales should not be allowed to remain on the sores, which should be kept pliable by the means of a lubricant. Boils were often caused by overfeeding with heating food. To counteract this green feed should be given, or plenty of bran, or, failing these, Epsom salts in the water. If it was considered necessary to place a bag under the collar it should first be folded lengthways. The collar should be put on and pushed forward up to the animal's head. The bag should then be placed tightly round his neck, and the collar slipped back over it, care being taken to see that there was none of the mane underneath the bag. Soaking the collars and placing them on wet was sometimes resorted to, to make them fit well. The paper was then discussed. Mr. S. Wild preferred to line the collar with moleskin. Mr. Gray would soak a new collar in water before putting it into use.

#### CLAYPAN BORE (Average annual rainfall, 16in. to 17in.).

March 1st.—Present: seven members.

**SAND IN HORSES.**—Mr. W. P. McCormack, in initiating a discussion of this subject, said that it was a great mistake, after having horses out in paddocks where there was little feed but dry stubble, to bring them in and immediately work them hard and long. Horses like this were often put into stables and allowed to gorge themselves with hay, chaff, and other feed. This caused colic, which, together with the sand all such horses would have in them, frequently resulted in serious trouble and often death. His experience showed that it was best to feed horses fresh from dry paddock feed very sparingly and work lightly for the first few weeks. At the first sign of sand a good opening medicine or sand powder mixed with a little chaff and bran, and given on an empty stomach was best. Sand was often an indirect cause of the stoppage of water horses often suffered from. This should at once be attended to, and in doing so, it often helped to pass the sand as well. He considered the best drench for horses affected with sand was new milk, honey, and coffee grains.

**COONALPYN (Average annual rainfall, 17.49in.).**

January 29th.—Present: 12 members and one visitor.

**SHOOT DESTRUCTION.**—Mr. Gurner initiated a discussion on this topic, and thought that constant cultivation was the best means of removing the shoots from the land. Mr. Oram advised slashing in February or March, but recommended using the fire rake at every opportunity. He thought that if time permitted it was best to cut two-year-old shoots and fire-rake young growth about March. He was in favor of the mould-board plough for clearing out stumps.

**EARLY GREEN FEED.**—Discussing this subject Mr. Hill said that on good clean land he would sow 1bush. of rye or 1½bush. of barley to the acre. Mr. Wall had been successful with a mixture of wheat and oats but did not advise putting in too much, as a great deal depended on getting it in quickly, well, and at the right time.

**COONALPYN (Average annual rainfall, 17.49in.).**

February 25th.—Present: 11 members and four visitors.

**PROSPECTS OF MIXED FARMING AT COONALPYN.**—Mr. Venning initiated a discussion on this topic, and placed fruit-growing first as a side line, and then dairying and poultry-keeping. The country was not far enough advanced for sheep. Members disagreed with this opinion, and considered that better crops would result when sheep could be kept.

**EARLY V. LATE SOWING.**—A debate on this subject was opened by Mr. Whitehead, who said that sowing should be commenced in March provided a suitable rain fell. The land sown first should be free from stumps and have the shoots cut, raked, and burnt, so that in the event of frost affecting the crop, it could be cut for hay. The danger of frost would not be very great when regular falls of rain were experienced. If sown late in bad seasons it was more than likely that the crop would not be high enough to reap, it was therefore evident that early sowing was best in spite of the chance of frost. This ensured that the crop would ripen early, and it could then be reaped before the shoots made sufficient headway to interfere with the stripping, as often occurred with late sown crops. When sown early and checked by feeding off and frosts, and thereby encouraged to stool, there was a better chance of a thick crop of stubble for a burn, which was most important, particularly where there were mallee shoots. If the stubbles were burnt the risk of "takeall" developing in the following crop was decreased. Mr. J. F. Pitman said late sowing was advantageous, particularly in a late season. Early sown crops, if only light rains fell, were in great danger of malting, and should these light rains be followed by a spell of dry weather, the crop would experience a big check. He considered that the danger from frost was practically eliminated with late sown crops, and further opportunity was given the farmer to work his ground up and clear it of stones and stumps before drilling.

**GERANIUM (Average annual rainfall, 16in. to 17in.).**

January 30th.—Present: 17 members.

**FALLOWING.**—This subject was dealt with in a paper by Mr. R. Nicholls. It was difficult, he said, to set down any hard and fast rule for working the land, as treatment that would suit one class of soil would, perhaps, be deleterious to another. He would commence fallowing as soon as possible after seeding operations were finished, and complete it by about the beginning of September, so that the land would get the benefit of the winter rains. Land which was ploughed later often became very loose, and was subject to takeall, black rust, &c. The depth of ploughing varied according to the locality, nature of the soil, rainfall, etc. He favored the stumpjump plough, cutting to a depth of 8in. On the red flats he would plough 5in. deep only, and on the sand rises about 5in. to 6in. Occasionally all land should have an extra deep fallowing. The ground should be kept open, and where there was a clayey subsoil it should be worked down. Where the subsoil was rubbly, the ground should be ploughed to a fair depth, so that the moisture might gain access. Any subsequent workings should be very light. He considered fallowing the most effective way of destroying weeds, shoots, etc., as each working pulled up a large number of young plants, and promoted the growth of others, which would be pulled up by subsequent workings. In his own experience 75 per cent. of the shoots on sandy loam that had been ploughed to a

depth of 5in. and then cultivated twice with a skim plough, were destroyed. Farmers in this district should, in his opinion, pay more attention to the system of dry farming. A discussion followed. Messrs. Pannell, Norton, and Jacobs agreed with the paper. Mr. Goldsworthy favored fallowing to a depth of 8in., and then using the harrows. Mr. Lithgow would work new ground very shallow, and then gradually work deeper as the ground became older.

#### HALIDON.

February 24th.—Present: 13 members.

**POULTRY BREEDING.**—A short paper on this subject was contributed by Mr. E. H. F. Meucke. He advised farmers who wished to adopt this industry as a profitable sideline, to procure say 1doz. pure bred White Leghorn second-year hens and one vigorous cockerel of the same breed. The male bird should not be placed with the hens until July. Hatching should be continued during August and September. The incubator should be placed in a room free from draughts and vibration, preferably one with a cement floor, and on a perfectly level stand. The incubator room should be maintained at as near as possible an even temperature. It would be wise to follow the instructions which were obtained with the incubator. When hatched the chicks should be left in the incubator for at least 24 hours before being transferred to the brooders. Cleanliness, warmth, fresh air, and careful feeding were essential to the wellbeing of the young birds. Too much heat was injurious. No more than 30 chickens should be placed in one brooder, which should have sand, ashes, or dry horse manure spread on the floor. At the beginning the young birds should be fed with coarse oatmeal and water (not too cold), and after a few days they could be given rolled oats, scattered amongst chaff to encourage scratching, and finely chopped green feed and meat at midday. They should always have access to grit and charcoal. The food should be given in small quantities and often. All sickly chicks should be culled out, and the pullets and cockerels separated. At six weeks they should be given in the morning mash consisting of one part of bran to two parts of pollard, lucerne chaff, and meat meal. The chaff and bran should be scalded, the meat meal added, and then be allowed to stand for a quarter of an hour, when the pollard should be mixed in. The mash must be fed in a crumbly state. At midday as much green feed as they would readily eat should be given, and the evening meal should consist of wheat and oats. Lucerne was the best green feed for fowls. He doubted whether breeding table birds would yet pay in this district on account of the distance to the market and the present high cost of food. A discussion followed.

#### LAMEROO (Average annual rainfall, 16.55in.).

February 27th.—Present: 16 members.

**MIXED FARMING.**—Mr. F. W. Eime presented a paper on this subject, in which he said that farmers with about 1,000 acres of cleared land should keep at least 100 good breeding ewes. He calculated that the benefit the land would receive from the sheep would amply compensate any expense involved. In addition he estimated that the lambs and the wool produced would show a net profit of about £65 a year. Six good cows producing an average of 6lbs. of butter per cow per week at 10d. per lb. would show about £80 a year, while 100 hens laying about 650 dozen eggs per year would produce about £20. A fair income of from £180 to £200 a year was thus made from by-products alone. The main item, he said, of course, was wheatgrowing, and this should always have the first attention. He advised early seeding in order that fallowing could be commenced early.

#### MINDARIE.

February 8th.—Present: nine members.

**SHOOT SCORCHING.**—In a short paper on this subject Mr. I. G. Lowe mentioned that the greatest check to mallee shoots would be given if they were cut between harvest and seeding, say, in January and February; and then fireraked. If not attended to until June, the shoots would have to be horseraked into rows and burnt. This referred to fallow land. In the case of land with a good stubble on it, a good fire-raking would destroy three parts of the shoots; the remainder could be cut after seeding. If a slasher were used, the best plan would be to cut off about two-thirds only of each shoot. The fresh growth breaking out from the remainder of the shoots would not be so vigorous as that which would break out from the stumps if the shoots were cut short off. A short discussion followed. Mr.

Lower favored a disc plough for destroying shoots. Some members preferred the slasher, whilst most agreed that a stubble burn and a few good ploughings were very effective.

**HARVESTING MACHINERY.**—Mr. M. A. Francis contributed a paper. He preferred the harvester, he said, as with this machine, one man could take off his own crop without employing labor. There was more waste with the stripper than with the harvester. He also considered that it was more profitable to take off the crop with the latter machine. Again, with the stripper there was a danger of the grain being damaged by the weather, whilst in the heaps. As most harvesters now had a carrier attached, the cocky chaff would not be wasted. If the stripper were used it was advisable to prepare a floor to prevent waste of grain. A piece of fairly hard loamy land should be selected, and a heavy plank drawn over it a few times.

#### MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

January 29th.—Present: 11 members and four visitors.

**MIXED FARMING.**—A short paper on this subject was read by Mr. A. Braendler. Farmers on small holdings, he said, would be well advised if they resorted to a few side lines to help increase their incomes. Enough stock of every kind should be bred to meet the requirements of the farm. He advocated keeping a few cows, pigs, and poultry, &c., all of which, if properly handled, would prove to be profitable. A discussion followed, most members being in accord with the ideas of the writer.

#### MYPONGA.

November 3rd.—Present: nine members and one visitor.

**WOOL CLASSING.**—The Hon. Secretary (Mr. F. Muller) read a paper on this subject, written by Mr. A. Hooper, in which he said that the two important points in the wool industry were honesty of get up and careful classing. There were many features visible to the buyer which might not be noticed by the grower which emphasized the value of careful classing. He advised that all Merinos and crossbred sheep should be shorn separately, and their wool kept apart. With the former it was only necessary to separate any extra heavy, matted or discolored fleeces which should be broken up and mixed with the skirts. In the case of crossbreds an extra coarse fleece should be put with the pure bred long wool. All pieces, bellies, locks and stains should be kept separate, and the other rolled up tightly but never tied with string. He advised avoiding all second cuts as being unprofitable.

#### PARILLA (Average annual rainfall, 16in. to 17in.).

January 28th.—Present: 14 members and one visitor.

**CARE OF HORSES' FEET.**—Mr. P. W. Lewis contributed a paper. In districts where there were no metal roads, he said, horses' feet were often neglected, much to the discomfort of the animals and loss to the farmer, consequent upon the reduced hauling power of the horses. The continued working amongst mallee roots had a tendency to break away the hoofs, which was often followed by sand cracks. This meant spelling the horse and often at a time when the animal could ill be spared. In most cases a little attention and trimming was all that was necessary to keep the feet in order. During harvesting and carting, and in the cases of hacks and harness horses he thought it advisable to shoe the animals. A discussion followed. Mr. J. A. Darby stated that the feet kept in better order on hard, stony ground. On soft ground there was a danger of the hoofs growing flat and splitting, and he advised shoeing the horses under such conditions. Mr. A. Camens recommended Stockholm tar for cracked hoofs. Messrs. W. Rush, J. Roachock, C. S. Foale, C. Moyle, A. J. Stevens, and G. Gregory also spoke.

#### WAIKERIE (Average annual rainfall, 8.89in.).

January 8th.—Present: 25 members.

**CHOICE OF FRUIT TREES AND PRINCIPLES OF DRYING.**—Mr. Ross spoke on this subject, and said that among the varieties of apricots Moorpark and Early Moorpark were the best. The Blenheim was a good faller, but was not so good in color as the Moorpark, while the Royal was not so good in weight or texture. The

St. Ambrose was oval in shape, and had one bluish cheek, was not affected by frost, was very slack in meat, tough in texture, a free cropper, dried out dark, and ripened with the Moorpark. The Tilton was a good canner, had a good yellow color, was hard right through, ripened very steadily, and hung a long time on the tree. It was a splendid cropper, a large size variety, and free from stone. The Riverside was a very heavy variety, and compared well with the Moorpark, and dried out heavier. It was always a good cropper, would not drop easily, resisted frosts well but colored white at the centre. Of the varieties of nectarines he considered the Stanwick, sometimes known as "Sugar Nectarine," the best drier. It dried very heavy, but would not dry whole. The Lord Napier was inclined to dry out light. The Goldmine was the best canner, a heavy cropper, and perfect in color, while the Newboy was similar. Of peaches he said that the Elberta was a poor canner, a good pitter, but subject to curl leaf. The Early Crawford was a heavy cropper, but doubled in fruiting, and was subject to split stone and not a good pitter. The Lady Palmerston was apt to crop too heavily. For three years it had taken the first prize for dried fruit at the Mildura Show. The Galway was the next best canner to the Elberta. The Foster was an uneven cropper in size, doubled and quadrupled in fruiting, was a bad pitter, of dark color, and an early variety. The Eclipse Clingstone was a splendid canner. Speaking with reference to the drying process he said that the trays should be 5ft. long and made of slabs. He advised one large and one small sulphur house of rubberoid or sheet tin, heavily coated to resist the fumes. The fruit must be ripe and full colored, but not squashy. Windfalls would not take sulphur well. The cup was full of juice when the sulphuring was completed, and the time involved should be four hours for slit fruit and 12 hours for whole. He recommended using 1lb. of sulphur to each 100 cubic feet, or 2lbs. of sulphur for each six-hour period. For whole apricots or nectarines the quantity of sulphur and the time should be trebled. Peaches were not dried whole. In drying it was important to keep the fruit free from dust. Mr. Musprat, of Renmark, had a lucerne patch encircled on three sides by a row of poplars between two rows of tamarisks, on which to dry his fruit. Stack drying, he said, was the best and quickest, but sun drying was preferred, the time to restack was when the juice had left the cups. The fruit should then be pliable but not brittle. In the discussion which followed Mr. Ross favored a venthole as it was necessary to secure a clean and thorough bleaching, to have a good draught. Mr. Lehmann had always used a venthole as it made the heat more even, and the sulphur burnt out more cleanly. A small window capable of adjustment when the sulphur was alight was good. Mr. Ross always used a camp oven to start the sulphur, and considered stick sulphur and flowers of sulphur inferior to sulphur matches. Mr. J. J. Vasey had used a portable hessian sulphur house. The hessian was coated with a mixture of 1gall. tar, 2lbs. pitch, 3lbs. resin, and was non-rotting with reasonable care. Ventholes, held by corks, were let into the ends, thus allowing a draught to play on the sulphur. The night was not a good time to sulphur, and peaches should be more heavily sulphured than other fruit. Mr. K. Dunstan was advised to use kerosine emulsion for spraying oranges affected with brown scale, known as honey dew. Mr. Ross said that the tendency in Lady Palmerston peaches to overcrop could be obviated by pruning.

#### WILKAWATT (Average annual rainfall, 16in. to 17in.).

January 30th.—Present: 15 members and one visitor.

**CARE OF HORSES.**—Mr. C. Sorrell read a paper on this subject, and said that the stable should be built facing east, north-east, or north, and so allow the sun to dry the stalls. Each horse should have its own stall, and be tied up some part of the day. It was advisable to let the animals loose at night in a small paddock, and so allow them plenty of exercise. They should be groomed each morning and watered before feeding, which should be given at regular hours, and never delayed.

**MANURIAL TEST.**—A manurial test was carried out by Mr. A. Neville, the results of which were as follows:—

| Plot.   | Manure Sown per Acre.         | Seed per Acre. | Yield per Acre. |
|---------|-------------------------------|----------------|-----------------|
|         |                               | lbs.           | lbs.            |
| 1 ..... | 56lbs. low grade super.....   | 45             | 12              |
| 2 ..... | 84lbs. high grade super.....  | 45             | 11              |
| 3 ..... | 112lbs. high grade super..... | 45             | 11 1/2          |
| 4 ..... | No manure.....                | 45             | 10 1/2          |

## WYNARKA.

January 10th.—Present: 16 members and one visitor.

**BREEDING AND CARE OF DRAUGHT STOCK.**—A lengthy paper on this subject was contributed by Mr. W. Richardson. In selecting a mare for breeding purposes, he said, care should be taken to see that she was sound in her feet, bone, and wind. She should also be roomy and wide in the hips. The sire to be used should possess good shoulders, good withers, good back and loins, and powerful quarters. He favored early foals, as they were able to derive benefit from the natural grasses; and it was important that both the mare and foal should always be well fed. The first winter was a very trying time for the colts, and every care should be taken of them during that period. He would wean when about six months old. The colt should be given regular rations of oats and wheat bran, for the first year, receiving liberal allowances, and afterwards being fed twice a day, with a quantity of mixed hay in addition. Linseed meal should also occasionally be given. Corn should never be fed except in the winter, and then it should be ground and mixed with finely cut chaff. He urged the necessity for grooming colts, as it stimulated the healthful action of the skin, and the animals became used to handling. At all ages they should be given plenty of exercise. Members discussed the paper, and were generally of the opinion that the feeding set down therein was rather too heating for this country.

**COOMANDOOK.**—January 30th.—A paper on the "Bulk Handling of Wheat" was read by Mr. R. Upton, sen., and was well discussed.

**MYPOLONGA,** March 17th.—A paper from the *Journal of Agriculture* on dairy cows and their ailments was read. In the discussion which followed Mr. Kleeman advised using a mixture of mutton fat, boracic acid and olive oil applied after milking for sore teats. It was agreed that the most suitable time to separate a calf from its mother was as soon as the calf had taken the first milk.

**NETHERTON,** February 7th.—**POSSIBILITIES OF THE NETHERTON DISTRICT.**—Mr. F. Byerlee read a hopeful paper on this question, and thought that with the return of good seasons and with cleared land, good payable crops could be grown. By dividing the farm into paddocks of, say, 150 acres to 200 acres the stock-carrying capacity of the land could be increased. The class of young horses seen on the farm here showed that the climate was suited to horse-breeding, and as all classes of stock were likely to be dear for some years to come, this should prove a very profitable side line. A small flock of sheep would be a source of income, and do the land good at the same time. The prevalence of takeall made it necessary to grow an occasional crop of oats on the land. In seasons when the market for oats was too low to give them any selling value, they could be utilised for feeding to the young horses, or when the feed was scarce in the paddocks they could be profitably fed to sheep. Poultry and pigs should not be neglected.

## SOUTH AND HILLS DISTRICT.

**CHERRY GARDENS** (Average annual rainfall, 35.03in.).

January 26th.—Present: 12 members and one visitor.

**PRESERVING FRUIT.**—An address on this subject was given by Mr. Thos. Jacobs. The process of preserving fruit, he said, was very simple, and also inexpensive, costing less than jam-making. The fruit should be placed in glass jars, packed closely, but not crushed. Luke-warm water should then be poured in. Then as many jars as possible should be stood on the bottom of the stew pan (or other convenient vessel), into which some water should be poured until it reached the necks of the jars. Between the jars and underneath them shavings or other suitable packing should be placed to prevent breakages. The fruit should then be boiled—a few minutes being sufficient for soft varieties such as apricots, plums, peaches, cherries, &c., and five to ten minutes (but no more) being sufficient for hard fruits, such as pears, apples, figs, &c. Immediately after boiling, airtight tops, preferably of glass, held on by means of a wire lever or spring should be placed on the jars. Indiarubber rings should also be used to ensure the tops being airtight. Bladder skin, if glass tops were not available, made a good substitute. It was immaterial whether stone fruits were placed in the jars whole or

otherwise. No syrup or sugar was necessary in preserving; pure water only being used. He considered that, when required for use, preserved fruit needed less sugar than fresh fruit.

HARTLEY (Average annual rainfall, 15in. to 16in.).

January 27th.—Present: 17 members and one visitor.

POULTRY.—A paper was contributed by Mr. W. Cross. He considered that with a little careful breeding and feeding poultry keeping could be made a very payable sideline. The poultry yard should be on a gently rising piece of ground if possible, so that there would be a natural drainage. The houses should face the east. Three breeding pens should be erected—one 9ft. x 40ft., with a house taking up 6ft. of one end. Into this 10 good hens should be placed with a cockerel. The other two pens should be about half the size of the large one. Into these he would place a few of his very best hens for breeding pullets for single testing, and cockerels for future use. A house and yard should also be erected for the laying hens. A house 20ft. x 6ft. with a 20ft. x 100ft. yard attached would be sufficient for 100 hens. He had had better results from working the incubator in a large room than in a small one. Culling out of the pullets and cockerels was necessary to keep up the standard of the flock. There was a danger when introducing new blood that the strain might be seriously affected; therefore every care should be exercised. Green feed was a very necessary article of diet to make the fowls profitable. He advised any that might be interested to visit the Parafield Poultry Farm, where many useful hints could be gained. A fairly lengthy discussion followed the reading of the paper. It was mentioned that there were disadvantages in having the fowlyard on rising ground, as the birds would then be assailable by hot winds and very cold weather. Some members considered that the birds should be given more room than set out in the paper. It was considered advisable to sow the green feed in small paddocks, and allow the fowls to pick at it. Grain would be best thrown in amongst cocky chaff, as the birds would then have to scratch and thus keep healthy.

MEADOWS SOUTH (Average annual rainfall, 35.52in.).

December 1st.—Present: eight members and one visitor.

ONION GROWING.—Mr. J. Philpot read a paper on this subject. He favored Brown Globe onions, as they were splendid keepers, of good appearance, and fair croppers. He preferred plants grown on the plains, as these did better in the hills than those locally grown. When growing his own plants, he selected a good piece of ground facing the east, and treated it plentifully with fresh stable manure. He sowed the seed in April, in beds of six rows, each row six inches apart, and left a pathway of 18in. between the beds. It was important to keep them free from weeds until transplanted. A little sulphate of ammonia applied on a damp day, accelerated the growth. When about a foot high he transplanted them into a dark, loamy soil, with a good clay subsoil, which had previously been ploughed to a depth of about 6in., worked to a fine tilth, and dressed with 5swt. of bone-dust to the acre. When planting it was advisable to cut off a little from the tops of the plants, as this enabled them to root more quickly. He placed the plants some 4in. apart, and to a depth of about 1in., taking care to press only the root and not the bulb into the ground. When the plants had obtained a fair hold in the ground, he hoed them about an inch deep, being careful not to disturb them in any way. In a dry year one hoeing was sufficient, but in a rainy season they must be hoed again about a month later, to keep the ground loose, and so allow the bulbs to expand, and to destroy weeds. When the tops began to die off it was time to pull them. If not pulled at this time they were liable to be scorched by the sun and rotted. If put into heaps with the tops uppermost, they were protected from the sun until they were dry enough to cart. When the plants were dried sufficiently, carting should not be delayed, as a fall of rain tended to make them shoot and rot. If he intended to store them for a time he used buckets or small boxes to cart them as this obviated bruising. They should be spread, never deeper than 1ft. on the floor of a rain-proof shed. He had found that land sloping east or south was the best for onion growing, and if the plants were put in the rows running north and south they secured the benefit of the sun in the middle of the day. He would not water the onions when they were growing if it could be avoided.

**MEADOWS SOUTH (Average annual rainfall, 35.52in.).****February 2nd.—Present: seven members.**

**RHODES GRASS.**—A bunch of Rhodes grass was tabled by Mr. G. T. Griggs. The seed was planted on November 23rd, and the seed bed sprinkled for three or four days after planting and kept moist. The grass now stood 4ft. high. About one month back he transplanted a few plants in dry ground, but little headway was made until after he had given them a good watering; they were now looking nice and green. Mr. Griggs considered that the ground should be well worked and the seed sown in the autumn or early spring to obtain best results.

**MOUNT COMPASS.****January 30th.—Present: 10 members and one visitor.**

It was reported that riddlers and green aphids had done extensive damage this season, especially to cabbages. Mr. Jacobs had checked riddlers by dipping his plants, when planting out, in a solution of arsenate of lead. The Inspector of Orchards had recommended spraying with tobacco wash, in order to destroy green aphides. He further said that the grub noticed by the secretary in the seed pods of a tree lucerne was similar to that found in peas, and was not the codlin moth.

**MILANG.****December 12th.—Present: 18 members.**

**PROFITABLE DAIRY FARMING.**—A paper on this subject was read by Mr. J. M. Yelland, in which he said that suitable land was an important factor in dairy farming. The ground must be capable of growing food suitable for producing milk. Land that carried clover, barley grass, &c., all rich in protein matter, would be the most suitable. Milking sheds and attendant buildings should be of stone if possible; wooden or iron sheds with a good fence round them were also suitable. The bails should be either bricked or paved, and the yard metalled or paved, preferably the latter, as it made cleaning so much easier. The use of lime could be lessened by having the north side of the shed open to the sunlight. The separating room, which should not adjoin the milking shed, should have a cement floor with a good slope for drainage. In all cases drainage should be through open drains; on no account should closed pipes be used. All pigsties should be as far away as possible, and should always lie to the south-east. Cows could be placed in two classes, i.e., milking strain and milk and beef strain. The latter were only profitable when beef was dear. The best cow to keep was the cross from a Jersey sire on a Shorthorn. This was a difficult breed to maintain, as by constantly breeding from Jersey bulls there was a tendency to a weakly constituted cow, and by breeding back with Shorthorn sires a comeback was the result. Holsteins were big milkers, and should be worth a trial. No dairyman could be successful unless he culled his cows well. In this district cows should be got in early, or they might not milk so well. The milk of doubtful cows should be tested occasionally. Heifers must be kept from the best cows, and the bull should be chosen from a good milking strain, and preferably from a large herd, as in such only the best bulls were generally kept. It was essential when choosing a cow to pick one with a well-developed udder, as it was on this that the quantity and quality of the milk depended. The milk veins should be large and well developed. The udder should not be fleshy, but firm, and should gradually diminish in size as the milk was withdrawn from it. The escutcheon was a valuable guide as to a cow's milk-producing capabilities. Cows should always be treated in a kindly manner, or they would not yield to their utmost capacity. It was necessary to always strip the udder. Regularity in milking should be observed. Cleanliness was a great factor in maintaining a high standard in the cream. The udders should be washed and the first milk drawn should not be mixed with the bulk. Natural pastures were always the best, but in winter when feed was short, it was advisable to feed hay or straw and cocky chaff mixed with bran and molasses. In summer lucerne, maize, sorghum, &c., should be provided. Cream should always be separated as early as possible, and never less than once a day. Separating should be done at a temperature of from 85deg to 90deg. Fahr., less cream was then wasted in the skim milk. Cream should be cooled as quickly as possible after separation, and on no account should warm cream be run into that which had cooled down. Marketing the milk was better than hand separating, as a more

uniform butter could then be made at the factory. Milk should always be weighed in order that a record of the amount given by the cows individually or collectively might be kept. This would also keep a check on the churn, and so give an idea as to the worth of milk per gallon. The comparison of these figures was a big help in culling cows. The dates of calving should also be recorded as a guide when drying cows off. Where winter grass was plentiful March and April were the two best months in which to have the cows to calve. Milking on the contract system had found favor on many farms, and the milking machine on many others. Labor, in any case, should not cost more than one-third of the gross returns. Success was only possible when the farmer was prepared to give careful attention to every detail in connection with the working of the farm. A good discussion followed.

#### MILANG.

February 13th.—Present: 25 members.

WHEAT-GROWING.—Mr. C. W. Ness read a paper on this subject, in which he said that the most reliable method of farming, in his opinion, was the three years' system. For farmers on small holdings, where this method was sometimes impracticable, he advocated a succession of fallow, wheat, and either oats or barley. Oats and barley grew well on wheat stubble, and were good crops to follow a wheat crop that had been affected with takeall. Another method was a succession of fallow, wheat or oats for green feed, barley, and then grass. It would be most profitable for the small farmer to crop portions of his land under each system. Fallowing should commence as soon as seeding was over, provided the land was not too wet and boggy. He advised working land to a depth of 5in., but the subsoil should never be turned up. After fallowing the land should be harrowed preferably when the surface was damp. Land should always be worked twice, particularly if overrun with stinkwort and other summer growth. Careful attention must be paid to the varieties of wheat sown in order to have seed suitable to the district; three or four varieties each year, he considered quite sufficient. If sowing for reaping it was best to pickle the wheat 24 hours previously, but if for hay the seed was better sown dry, as a stronger plant would develop. He considered that for hay early hard-strawed wheats were most suitable in this district, as a good crop of straw, if not of grain, always resulted. Haystacking should always be finished before stripping commenced. He had had good results from Gluyas, King's Early, and Newman's Early for hay, and from Marshall's No. 3, Federation, Yandilla King, and Gluyas for grain. A dry, free-running manure, as high in phosphate as procurable, was best and cheapest. He usually sowed 1cwt. manure to the acre for grain, and from 1½cwt to 2cwt. for hay. He did not think it advisable to feed off a crop intended for hay unless it became rank or went down early in the season. A crop intended for grain, however, might be fed off by sheep to advantage. Wheaten hay should be cut as soon as the grain became doughy, and oats when almost ripe. The crop should be stooked, four sheaves wide, as soon as possible after cutting, particularly if the weather were warm; the hay should then be ready for stacking in 12 to 14 days. It was a good plan when stacking to sprinkle each layer with a strong brine as it tended to keep the hay mellow and added salt, which was always an advantage in a dry country. In harvesting grain he preferred the stripper to the harvester in light crops or in stumpy ground. The harvester was most useful on clear, level ground, and in a heavy crop. A good discussion followed.

#### NARRUNG (Average annual rainfall, 17in. to 18in.).

January 29th.—Present: 15 members.

CO-OPERATIVE BUTTER FACTORY.—Mr. Richards contributed a short paper. He was of the opinion that the dairymen of this district would greatly benefit if a butter factory were established there, but members generally having in mind the number of such factories that had been opened and then failed, and in view of the fact that the rivalry existing between the firms competing for their produce would ensure their receiving good prices, did not favor the establishment of a butter factory at present. Mr. Richards also favored the co-operative purchase of pure bred dairy bulls. By this means the best animals could be obtained. Members generally favored keeping their own bulls, as a high class yearling bull could be obtained at a very reasonable price.

KANMANTOO, January 30th.—Mr. H. G. Pym read a paper on the drought, and gave as his reason for the starvation of stock that during the last seven to 10 years food which should have been conserved had been wasted. His experience had proved the drought-resisting qualities of wheat as compared with oats. One benefit which came from the drought was that it gave the land a rest, and so was conducive to good crops in the future. The paper was followed by a discussion.

LONGWOOD, January 20th.—After an inspection of Mr. Roebuck's garden a general discussion took place on the best time and varieties of green feed to plant.

MACGILLIVRAY, February 27th.—In reply to a question as to the proper time to cut grain for hay, members were agreed that for oaten hay it was best to leave it until fairly ripe, but wheaten hay was best cut on the green side. It was agreed that green feed as a cure for colic was preferable to drenching.

MOUNT PLEASANT, March 12th.—AFRICAN BOXTHORN.—Members generally were agreed that this was a useful hedge, and not liable to become a pest.

### SOUTH-EAST DISTRICT.

MOUNT GAMBIER (Average annual rainfall, 32in.).

January 9th.—Present: 17 members.

In a paper dealing with "Misses or blanks in the potato crop," Mr. Rodney Fowler said:—"It is not an uncommon occurrence to find in the potato fields that although the rows have been regularly planted with sets which to all appearances seemed healthy and sound, when the shoots appear above ground there are a great many gaps among them. This leads to very serious losses, and waste of ground and time, as the field requires just as much cultivation as if the full number of plants were in the rows. The only reasonable explanation is that the seed must be faulty in some way. For some time it has been advocated that all potato seed should be sprouted before planting, and if this method could be adopted a great deal of the trouble would be done away with, as one of the main causes of blanks in the crop is a disease known as "thready eye" or "spindle" disease. Potatoes affected by this produce numerous slender threads or pale-colored shoots, or else produce minute tubers ("mules") close to the eye, without any shoots at all. Even in cutting a potato for seed, there is internal evidence of it. A network of dark streaks will be seen throughout the flesh of the potato, as well as the usual vascular ring. The exact cause of this disease is somewhat obscure. It has been attributed to a parasitic fungus, but no definite organism has been found causing it. There seem to be various causes at work, and bad or defective nutrition is the chief, leading to poverty of starch in the tubers. It has been found by experiment that where potatoes were planted in very dry soil, so that only small and unripe tubers were produced, the plants died prematurely and the entire crop suffered from the disease. And again, when planted in cool, moist soil, with luxurious growth at the start, followed by a sudden stoppage, owing to extreme dry conditions, similar to those which prevailed in most of the fields here last season, the crop suffered very considerably from this disease, even up to 50 per cent. being affected. So that the fact that this disease seems to be controlled by conditions of soil and climate, and that the seed taken from a crop grown under unfavorable conditions is likely to be badly affected by this trouble, shows how necessary it is that the seed should be allowed to develop certain indications of the disease, if it has it, so that it may be rejected and not planted. It is commonly argued that seed showing indications of "thready eye" is run out or degenerated, with a reduced vitality, and accompanying this is a want of capacity to elaborate the ferment necessary to render the starch grains in the potato available for plant growth. The action of manures has not been found to have any appreciable influence on the disease, but the presence of lime has diminished it considerably, sometimes as much as 50 per cent., which is another argument in favor of liming our soils. When this disease is very common, a change of seed potatoes from a different kind of soil should be tried, and of course

affected potatoes should not be planted. Another disease that accounts for a number of misses in the potato field is that known as "rhizoctonia," which means, literally, root destroyer. The black specks, commonly taken for particles of dirt adhering to the potato, are so common now on potatoes supplied for seed that it is difficult to get a quantity of seed that is free from them; and the disease has for so long been regarded as of no importance that tubers so affected are regularly planted. But it is becoming a question whether in the future more notice will not have to be taken of this trouble. Mr. McAlpine points out that this seemingly harmless black spot on the potato may produce a fungus that will cause the young shoots to rot and die off at the stem, or it may cause the bark to peel off round the stems of more mature plants, which makes the tops more luxuriant, while the tubers are either not formed at all, or are small, owing to the sap in the tops not returning to nourish them. Another result sometimes is the formation of small green potatoes, on the stem above the point of injury. This is a fairly common occurrence in the potato field, as is also the presence of potato tops showing luxuriant foliage, but with the top portion wilted, whilst on the plant below the foliage the stem will be found coated with a white mould, the reproduction stage of the fungus. The fungus is said to thrive well in sour soils, and therefore liming will be beneficial, but will not entirely prevent it. As the fungus is suspected of developing on weeds, clean cultivation is also necessary. From experiments carried out in Victoria it has been found that clean seed on clean land will produce a clean crop, and that corrosive sublimate (2½oz. to 15galls. of water) is an effective solution in which to steep the seed. Two other ways in which a potato planted may fail to grow are it may either remain dormant and send out no shoots at all, or the shoots may be so feeble in their growth that they soon die. This failure is usually attributed to degeneracy of the potato, but this may not always be the case, as has been proved by experiment; tubers which had refused to sprout under ordinary conditions growing well after being subjected to a temperature of 70deg. Fahr. in a forcing pit. Again, when sets are too mature they frequently do not decay, and this may cause numerous gaps in the crop, so that from the various causes enumerated it would seem, that to be sure of a good crop, with a likelihood of freedom from disease, the process of "greening" or "boxing" should be adopted, and more care taken to reject as seed potatoes showing evident signs of disease. Another point to be remembered in connection with this is that once such diseases as "rhizoctonia," scab and red worm are planted in the soil it is not an easy matter to clean the land again, as it has been repeatedly proved that these diseases have other host plants, that may keep them in the fields for years." An interesting discussion followed the reading of the paper.

**DAIRYING.**—Mr. H. G. Wheeler read a paper. He mentioned the necessity for ascertaining whether the holding on which it was proposed to practise dairying was suitable for the purpose, and the paper continued as follows:—"Every practical farmer knows that keeping his cows warm means a saving of food and an increase in the production, just as assuredly as keeping them cold means an increase of food and a decrease of production. It has been demonstrated beyond doubt that rugging is the most effective, and also by far the cheapest system to protect cattle from the cold weather. Cows that are rugged increase their milk yield on a smaller quantity of food, and maintain their condition. When cows are reduced in condition by exposure to the cold weather during the winter, the most profitable portion of the spring expires before the butter-producing capacity is once more restored. It is almost impossible to get a first-class herd together in such a good dairying district as ours. The reason for this is that the breeders are not careful in selecting a pure sire of the best milking families. The crosses I favor are the Ayrshire and Jersey, and the Ayrshire and Shorthorn milking strain. From either of these crosses one would get both quantity and quality of produce. Heifers should not be allowed to breed before they are two years old. Kind treatment is very necessary with dairy cows, as heavy milkers are usually very nervous. Pig-rearing is also very profitable with dairying. The sties should be a considerable distance from the milking shed. Lucerne should be grown for summer fodder. It is ready to cut as soon as the grass dries off; and it helps to keep the cows in full profit. It is less expensive than other fodders, for once established, it will last for a number of years. I have a plot that was sown 14 years ago, and it is as good to-day as it was the second year. Mr. J. Davidson also addressed the meeting. He advocated rugging the cows in this district, and urged the importance of growing fodders.

NARACORTE (Average annual rainfall, 22.60in.).

November 14th.—Present: 22 members and one visitor.

**MOST SUITABLE TYPE OF HORSE FOR THE FARM.**—Mr. Sullivan (Kapunda) contributed a paper as follows:—"Let us briefly review the types of horse obtainable in Australia and of most use to us as primary producers, &c. In recent years there has been brought to Australia what is known as the English Shire horse. This is undoubtedly a very fine type of animal, and one which will do a goodly quantity of work. It is of a massive appearance, and capable of shifting heavy loads. It is heavy boned, and possesses a large quantity of hair below the knee and hock, but while this type of horse possesses good qualities, I am of the opinion that he is not suitable to Australian conditions, in so far as he is generally a slow mover, and not possessed of the hard, flat bone and sound hoof of that other magnificent type of horse, the Scottish Clydesdale. This is, in my opinion, the grandest all round type of horse in the world. He is descended from the hardy mountain breed which roamed the heathery hills of Scotland for hundreds of years before being transplanted to these southern lands. He may be described as being extremely active, standing about 16 hands high, and sometimes on the leggy side, but I hold the view that a horse is in many cases a better animal for being on the tall side, as he will outwalk the shorter horse in the majority of cases. The fashionable color is dark brown with two white hind feet, a white stripe running from the muzzle to near the ears, widening between the eyes. The body is short, but very deep, compact and strong. The chest is wide, and lung space roomy; arms strong, and the legs straight. The thighs are very deep and muscular, and the barrel round, and the ribs closely joined home near the hook bone. The neck is of nice length and finely arched, showing uncommon depth from the bottom of the chestline, slanting upwards to the top of the withers. The head is fine and tapering, the ear small and erect, and the eye prominent and lively. This is a fair description of the Clydesdale, other than to say he is possessed of fine silky hair, flat bone, and good hoofs when not overgrown through heating foods. This, then, is the type of horse, in my opinion, which stands right out as the most suitable one for all kinds of farm and road work of a laborious nature, and it well behoves the farmers of Australia to generously patronise those who expend large sums of money in the importations of good sires into their district, and once and for ever do away with the stupid idea that good results will come from mating with faulty stock. One more phase of this question, and I am finished. The South Australian Government compels every horse shown at a show to subsidises to have a certificate of soundness awarded by a veterinary surgeon. This is a good thing as far as it goes, but is it not madness laughing wild to allow the animal possessed of hereditary unsoundness to travel the district and undersell the man who goes to the expense of purchasing good animals, as is being done in every district in Australia. If the horse is hereditary unsound, even though it may cause a little hardship in cases, it would be amply justified that he should, in my opinion, be rendered useless for stud purposes. The final question is how to judge a horse. The best answer I can give is to work him for three months."

**SYSTEM ON THE FARM.**—The Hon. Secretary (Mr. W. H. Smith) read a paper from which the following is extracted:—"In travelling around I have noticed on some farms a decided lacking of system or care. Time does not seem to be valued as it should be, and things generally seem to be in a continuous muddle, and a big wastage is going on, such as no up-to-date or practical man could afford to let go on. It is only by systematic and careful management on the farm that a thorough success can be achieved, and the finances kept in a healthy condition. A farm should be looked upon and worked throughout the year strictly as a business proposition, and every endeavor made to save time, labor, and wastage. Soils vary in almost every district, and likewise, to a lesser degree, climatic conditions, and so it follows that each and every individual agriculturist must study the soil on his particular holding, and grow crops and varieties to suit the soil and climatic conditions. If you have not had the opportunity of learning the composition and classification of soils, take the first opportunity of doing so. Get a good book on the subject, and study it. You can also get samples of your soils analysed for a very small cost. Either the book or the analysis will cost you but a few shillings, and you will find that it will put pounds on to your banking account. Bring commonsense and judgment to bear on what you learn from the analysis, or from the works on the soil, and cultivate your land in a systematic and scientific manner, supplying that which is deficient, and being careful not to

overload with what may already be there in abundance. As soon as you have your land securely fenced, cleared, and divided up adopt a system of cropping that you consider will be the most successful, and, at the same time, carry on in a small way a few experiments from year to year in regard to the various cereals, depths of planting, quantities and varieties of fertilisers, &c. Watch your neighbor carefully. If he is more successful than you find out the reason, and do as he does, or go one better. It creates friendly rivalry, and it pays, too. Read anything and everything appertaining to agriculture. Throw aside that which you think is inferior to your own system, and adopt all improvements within your power and means. When you start the plough keep it moving all the time. It doesn't pay to stop it to lop a tree or chop up a stump. Get someone else to do that if you cannot arrange to have the paddock clear beforehand. Use the largest plough you can, taking into consideration the strength of your team and the class of soil. If you are using two double furrow ploughs, or a two and three furrow, and you know that you could successfully work a four or five furrow implement, get rid of the little ones as soon as you can, as you are losing money. One man can work a five-furrow just as easily as he can a two or three-furrow plough, and the change will put pounds into your pocket each year. That has been my experience, and I keep a detailed account of the exact receipts and expenditure of every crop that I grow. Always carry a box on your plough containing a few sundries, such as spare nuts, bolts, eyebolts, S hooks, wire, &c.; it saves time. The same applies to all implements. Axle grease and oil are cheaper than machinery parts, so do not let your machinery cry out for them. Look after your machinery well. Keep them well cleaned; overhaul them and get to know them, and keep them well protected when not in use. A few pounds spent in timber and galvanized iron will save its cost many times over in the machinery bill. Thatched sheds are ugly, they harbor vermin, they are often leaky, and you have to keep patching them up and repairing them; they are risky for fires, and you cannot fill tanks from them. Their one and only compensating factor is that they are cool; but a galvanized iron shed for implements is cool, too, if you build it correctly. Oil your harness at least twice a year. A few shillings spent in neats-foot oil will save pounds in leather. Hang your working harness in or by the stall of each horse; don't throw it down in a heap on the floor, or in the corner. Give each horse a number, and put the number on the harness, or else the initials or name of the horse. Keep a few mares to help to keep you, and to keep up the team strength; it is cheaper to breed than to buy. If you have got a jib or a kicker pass him out. If you are working a fair distance from the homestead and water is available it will pay to take your own and the horses' lunch out with you, because you can be working instead of walking. Treat your horses as they should be treated, viz., with kindness and consideration. Stable them, feed them well, and groom them. Erect all your sheds, yards, and buildings in systematic order, and so save space and time; do not scatter them about. Have gates or doors leading from one to the other. See that your chaffhouse is large enough to hold a third, or half a year's supply. It doesn't pay to be cutting chaff every two or three weeks, especially in seeding or harvesting times. If you have a bore or well don't waste two or three hours every day pumping or drawing water, as it means over a full month wasted out of every year. Get a windmill, or an engine (if it can be used to better advantage), and let them do the work. See that your trough is in the most convenient place, the cost of a few feet of piping and taps is soon made up in time saved. Get a few feet of piping and utilise the overflow of the tank, either on the kitchen garden, fruit trees or lucerne. It costs nothing for the wind and only a few pence for oil, so let the mill keep going. Don't keep cows, make them keep you; weigh their milk and test it and throw out the loafers; you will make more money out of five good cows, well kept, than ten second raters half kept, and they take much less handling, too. Look after your sheep well. You cannot afford to keep ticks or lice, or even blowflies. Do not let your sheep starve because they cannot see where the feed or water is. Produce a uniform class and quality of wool, and always strive to improve your clip. Do not overstock. Don't keep any fowls over three seasons. Erect proper yards and houses as soon as possible, as they save your time, garden, and the looks of your machinery or buggy, and also your horses' feed, to say nothing of your temper and eggs. Don't burn up any more timber than you can possibly help, but cart it up to the house or sell it. Get together a good set of tools. Keep them in a box or on a rack, and make it a practice to see that they are always to be found in

their place. Keep gates and fences in good order. It doesn't pay to put up make-shifts. Build the haystack as close as possible to your chaffhouse, in order to obviate waste time carting hay in drays and wagons to the cutter from the stack. Handle the hay as little as possible. Cover your stack well, and you will find that a galvanized iron shed will work out the cheapest. When working your teams always harness and unharness the horses at the nearest possible point to your stables; it saves a lot of walking and time. Make it a hard and fast rule to always carry a small memorandum book and a short piece of pencil. Jot down under their respective headings all things that come under your notice requiring attention, such as fences to be repaired, wet day jobs, goods to be ordered, machinery parts to be replaced or repaired, and so forth. Put down how long it takes you, or the assistant, to plough, harrow, drill, &c.; how much seed and super. you use for each crop; the number of horses, &c., used in each implement. Carefully enter and check all this, together with the cost and returns of your harvest, and you will very soon find out which crop pays you best or where a leakage is going on. Always keep a diary going, and enter up all items of importance, such as times of ploughing, sowing, harvesting, &c., fowling dates, and all stock births, dates of purchases, payments, &c. Keep all your receipts and letters in their order, either on a file or paper clip, and keep a simple set of account books, and carefully enter all items of receipts and expenditure. When it is too wet to work outside look up your wet day list and overhaul and clean up your machinery, mend your sacks or harness, clean up your sheds, do your soldering jobs, &c., Do not depend on only one line for your income, but have several sources. Study up the market reports well and endeavor to catch the good prices, and sell to the best advantage. Buy in the best markets, and, as far as in your power, adopt the cash system for your sales and purchases. Always strive to do better than you did last time, and remember that a good article or a conditioned animal will always sell, and they make a good name and business for you."

#### TATIARA (Average annual rainfall, 19in.).

February 6th.—Present: nine members.

**HORSE BREEDING.**—A short paper under this heading was read by Mr. C. W. Saxton. In his opinion best results were obtained by breeding from a sire of not less than seven years of age. He should be of medium size, masculine in appearance and perfectly sound. The mare should be at least four years old. Only the best mares should be used for breeding purposes if satisfactory results were to be obtained. The paper was discussed, and several members were of the opinion that a mare at three years was old enough to be used for breeding purposes.

#### WIRREGA (Average annual rainfall, 19in. to 20in.).

March 6th.—Present: 10 members.

**CARE OF FARM SHEEP.**—Mr. W. R. Fairweather read a paper on this topic, in which he said that one of the first things to be attended to was the water supply. It was best to avoid watering at dams, unless certain of the purity of the water. There was no doubt that if sheep drank plenty of water they would keep in good condition. Blowflies had caused serious losses to the farmer. To prevent lambing ewes being attacked it was necessary to have them breeched and crutched before lambing. Care should be taken during this operation not to worry the ewe more than necessary. If already affected, it was advisable to spray the sheep with a solution of dip, which would probably kill all eggs of the fly. Dipping should always be carried out after shearing, in order to avoid handling the sheep twice. In addition to killing the tick, this operation cleaned the skin. It was best to cull breeding ewes at shearing time, as otherwise it was often difficult to distinguish them from inferior sheep. In his opinion, breeding should commence when the sheep were two-tooth. It was unprofitable to keep sheep another year, even though at one year they might not be such good mothers. Dealing with the care of skins, he said that no blood should be allowed to get on the neck of the skin, as it gave a bad appearance to the wool. The sheep should be skinned as soon as killed, in order to prevent blood from collecting in the veins and staining the hide. The value of a skin was greatly reduced if cut, and in

consequence it was better to use the hands than the knife. As soon as the pelt was firm it should be thoroughly painted with a weevil wash. Skins should never be dried in the sun, but placed in the shade over a rail, hung from head to tail. In selecting fat sheep three points were to be noted—(1) The general appearance, (2) well-covered loin and ribs, (3) a fat tail. An interesting and profitable discussion ensued.

**TATIARA, January 2nd.—THRIFT.**—Mr. A. A. Fisher read a paper on this subject, in which he deplored the waste that had been common on farms in good years. If farmers to-day had the straw and cocky chaff they had burned then, and the tons of hay that had been spoilt by rain, which a little care might have saved, they would not be appealing to the Government for assistance.

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

## STOCK INQUIRIES.

Replies by Mr. F. E. PLACE, B.V.Sc., M.R.C.V.S., Veterinary Lecturer.

"R.J.F." asks how to treat a cow in a case of retention of after-birth.

Reply—If a cow has not cleaned in 48 hours it is advisable to take a split stick and wind the cleaning round it, keeping a steady strain on it till the cotyledons or attachments to the womb are felt to give way one by one, but generally, if 1lb. of Epsom salts, 1oz. sulphur, and 1oz. ginger are given in a quart of warm beer the afterbirth will be expelled. Under the above proceedings syringing will not be necessary, but if resorted to either soda or Condy's crystals should be used alone, a handful of the former to a kerosine can of water, or as much as will lie on a sixpence of the latter. If very obstinate the arm should be first disinfected, and then inserted and the cotyledons broken down by crushing them singly between the bent knuckles; not the finger nails.

"S.G.W." asks the food value of lucerne compared with bran and pollard.

Reply—Supposing a perfectly digestible food were called 100, bran equals 53.76, pollard 49.15, lucerne hay 30.24, green lucerne 9.33. So that a pound of bran could be substituted by about 1½lbs. of lucerne hay, or a pound of pollard by about 1½lbs., or a pound of bran by about 5½lbs. of green lucerne, or pollard by 5½lbs.

"W.H.N." had eight horses die within a fortnight after being put in paddock of saltbush and buckbush. Remaining horses were taken home, but did not put on condition, and one is suffering from intermittent paralysis.

Reply—Blood worms. Give Fowler's solution of arsenic, two table-spoons once a day for a month, also a teaspoonful of sulphate of quinine twice a day. The deaths of the other horses were probably due to worms and change on to bush feed, to which they were not accustomed.

"J.R.B." seeks advice concerning filly, 3 years, which is poor from lack of feed, and has swellings above stifle and under belly, and a difficulty in getting up.

Reply—The swellings are glandular, and arise from anaemia, due to March flies, possibly. Give Fowler's solution of arsenic, two table-spoons once daily for a month, also a teaspoonful of sulphate of quinine twice daily for a similar period.

"W.J.T." asks treatment for horse suffering from sores on mouth, similar to those caused by grass seeds, but larger and harder.

Reply—Probably necrosis following grass seed sores. Try dusting with equal parts alum and bluestone; apply every few days.

Members of the Northfield Branch of the Agricultural Bureau inquire:—(1) Cause of death of number of horses which it had been reported were treated with arsenic; and (2) the value of molasses as food for stock.

Reply—(1) In the case referred to crude arsenic was administered in fatal doses. A tablespoonful of Fowler's solution contains two grains of arsenic, and four grains are a safe dose. The reason for stopping at the end of a fortnight is that the liver eliminates it from the circulation and accumulates it in itself, paying it out again when the dosage stops, so the interval is advised to obviate a small risk. (2) In itself molasses has but a small feed value, as it must be diluted with roughage to be digestible, and anything over 5 per cent. of the weight of fodder given in molasses is a waste of the latter, as it then hinders digestion instead of helping; in this latter condition it does very materially improve the condition of stock to which it is given by making food more palatable and easier of digestion, so that greater use is made of the food material.

"M.E.M." asks treatment for horse with greasy heels which are constantly flyblown.

Reply—Give a tablespoonful of sulphur in feed once a day for a fortnight. Mix 1 part benzine to 5 parts olive oil, and apply twice a day to the legs; when all the maggots are killed and improvement commences apply once daily a lotion made of sulphate of zinc  $\frac{1}{2}$  oz., sugar of lead  $\frac{1}{2}$  oz., benzine  $\frac{1}{2}$  pint, methylated spirit  $\frac{1}{2}$  pint.

"E.D." asks information as to treatment of stallion colt which he thinks has dislocated shoulder.

Reply—Dislocation of the shoulder practically never occurs in the horse, for anatomical reasons, and from the description it is more probably a fracture, which is of frequent occurrence. Surgical treatment should only be attempted under the direction of a qualified veterinary surgeon who has seen the case, as the faint clicks point to fracture. A prolonged rest with application of Stockholm tar occasionally over the seat of injury would probably be the best treatment; no rope or force. If it were dislocated it could not be replaced without putting the beast under chloroform.

"A.K." states his horses have too frequent and profuse urination, and asks for advice.

Reply—Possibly due to eating thistles; try a tablespoonful of bicarbonate of potash in food twice a day for a few days, and if improvement follows then once a day for a few more days; 10 drops of tincture nux vomica morning and evening will also help.

“C.A.H.” asks treatment for horses with sand.

Reply—A remedy which meets with much approval is a pint or so of new milk with a pound of honey warmed up in it. Many horses take this readily, mixed with feed; others have to be drenched. The remedy may be repeated in a day or two if thought necessary. Green feed coming along will probably do more than powders, &c. The rationale of treatment for sand is to create a large quantity of fermentative gas bubbles which break up the sand, the external rubbing having the same effect. It is desirable to get the bowels relaxed, but raw linseed oil, in the writer's experience, is not very satisfactory, as it glazes over the surface of the sand, and protects it from the action of the gases. A teaspoonful of powdered nux vomica may be given in the feed once or twice a day, but it will probably be found that 10 to 15 drops put on the tongue morning and evening will have a better effect (tincture), and this drug being a bowel muscular tonic and stimulant is useful. A pint of yeast or a bottle of beer very often starts the sand when other remedies seem ineffective. Either are frequently taken in feed, if not may be given as a drench. A tablespoon of black gunpowder in feed will do no harm, and may bring about a shift. This can be given twice a day for a few days.

“F.J.K.” has sow which became paralysed in hindquarters a few days before farrowing; her litter is healthy, but she is still down.

Reply—A form of parturient paresis. Give tincture nux vomica, 10 drops three times a day in a little milk in the trough, and rub loins with mustard or liniment once or twice a week. After recovery give 2ozs. crushed castor oil seeds in milk once a week for a fortnight.

“E.G.” asks treatment for cow with warts on teats; they are also sore.

Reply—Apply castor oil after milking one day and vinegar the next; keep up this for a week or two. If this does not succeed apply daily an ointment made of tincture thuja 1 part, vaseline 10 parts.

“F.J.B.” had horse die as result presumably of severe colic brought about by eating old straw. He sends results of p.m. examination.

Reply—The rupture of the diaphragm was brought about by the abdominal distension caused by the fermentative gases. The patches of inflammation were due to bloodworms. In event of similar case give raw linseed oil 1 pint, gin  $\frac{1}{4}$  pint, essence of peppermint 25 drops, and repeat in two hours if necessary. Rub flanks and ribs well with embrocation or mustard.

“J.R.B.” asks advice concerning a mare suffering from colic with staggering and scouring. She improved under treatment for colic and sand, but was inadvisedly allowed chaff too early, and strained and everted the anus or hind gut.

Reply—The bowels must be kept loose by 3oz. or 4oz. doses of Epsom salts once or twice a day in bran, preferably as a mash, if she will eat it. The protrusion being as large as a bladder will be difficult to return, but it must be thoroughly soaked in warm water with a handful of washing soda to the bucket, then well greased with lard or cream or lanoline, preferably containing two grains of cocaine. It must then be bandaged and massaged so as to get it back into the rectum, which should be emptied by hand; a beer bottle filled with warm water and corked should then be gently inserted neck foremost to act as a pessary, having a piece of tape tied round it, and protruding so that it may be pulled out when the mare wants to pass dung again. An ounce of chloral hydrate should be given as a drench to keep the mare drowsy. A relapse may be expected, and the same treatment repeated.

“S.E.” has foal which was bitten about three months ago by another horse on the withers; the wound does not heal under ordinary treatment. The lump is large and hard.

Reply—Although very unusual in so young an animal, this is a case of fistulous withers; the place must be probed and opened out, the dead tissue removed, and then the operation wound irrigated with cold water for an hour a day for a week or two, and the iodine spirit applied.

“J.F.D.” asks the advisability of using an anæsthetic when castrating an aged stallion.

Reply—Personally the writer does not favor a general anæsthetic for the operation, the after effects of the drug being much worse than the operation, and the tendency to excessive bleeding greater. Chloroform would be preferable, but is dangerous in inexperienced hands. If desired to lessen pain half a grain of cocaine dissolved in 20 drops of water may be injected into each side of the scrotum a few minutes before casting, or an ounce of chloral hydrate dissolved in a pint of warm water may be given as a drench or injection enema an hour or two before operating. The emasculator is preferable to the iron, but must not be removed too quickly from the cord, which should be twisted three times before applying the instrument.

“T.B.” lost a mare through blood poisoning developed from a stake in her foot. He asks advice for similar cases.

Reply—Remove stake as quickly as possible, pare out the external opening of the wound, and thoroughly cleanse with some disinfectant, such as washing soda, a handful to a couple of gallons, put on a dressing of Stockholm tar, and a bag over all; if the animal becomes feverish give a packet or two of Epsom salts in each feed. Keep wound clean and healthy, but not too wet. Spirits of iodine, as so often recommended, forms a good dressing also.

“W.S.” wants to know if it is advisable to tap horses suffering from windy colic.

Reply—As a rule it is not advisable to tap a horse for flatulent colic on account of the animal's proneness to develop peritonitis. When performed the operation is carried out at the highest point of

the swelling of the flank on the off side with a trocar not larger than a grass stem. At one time the operation was very popular, but went out of use on account of bad results some 20 years ago.

"C." has seven horses which got at wheat; five died and two are very stiff in legs. He asks if the latter will be good for work again.

Reply—The stiffness is laminitis or founder, which so often accompanies severe constitutional upset, and it is to be feared that if they recover they will only be fit for slow work on the land, and will not be able to do road work. Keep the feet in clay pug swabs or cold water, if the horses are able to stand, for several hours a day, give tincture aconite, 10 drops, three times a day for a week, and then tincture arsenicum similarly, as they improve. Stockholm tar swabs may be substituted for the pug. For horses found to have got at wheat  $\frac{1}{2}$ lb. baking soda in a quart of milk is recommended, also free drinking and copious enemas.

"A.H.S." has a buggy mare that scours badly when driven. He asks treatment.

Reply—Never feed within two hours of driving, and restrict water supply, not allowing any drink for several hours before driving, but allow small quantities on the road with bit in mouth. Give a pint of lime water twice daily with food for a fortnight or so.

Replies by Mr. C. A. LOXTON, B.V.Sc., Government Veterinary Surgeon.

"M.C." asks treatment for mare with greasy heels and how to rid of lice on animal.

Reply—For greasy heels use the following preparation, painting on daily:—Formalin 1 part, methylated spirits 5 parts, glycerine 10 parts; mix. Those horses which are not responding to fair feeding should have the ration improved, and should receive one tablespoonful of Fowler's solution of arsenic in their feed daily for 10 days. Destroy the lice by applying kerosine emulsion as follows:— $\frac{1}{2}$ lb. soft soap dissolved in one gallon of warm water, add 1 pint of kerosine, mix thoroughly.

"Lavinda" has mare which is losing hair from tail and mane. He asks treatment.

Reply—The condition is due to a skin parasite. Use the following liniment:—Benzine 1 part, olive oil 5 parts; mix. Lucerne hay better fed to horses as chaff. Quantity depends upon work and class of horse.

## FORAGE CROPS IN THE SOUTH-EAST.

[Address by the Director of Agriculture (PROFESSOR ARTHUR J. PERKINS), at the Conference of South-Eastern Branches of the Agricultural Bureau.]

### INTRODUCTORY.

I have been asked to address you on the subject of "Forage Crops;" and in this connection very naturally you have had in view the peculiar requirements of your own district.

Now let me say at the outset that in dealing with a subject of this kind I find myself at a disadvantage in that I have not as yet had the opportunity of farming in your particular district; and whilst in the North I always feel quite at home, I shall, for a time at all events, find myself somewhat awkwardly situated in the South-East. Let us take it, therefore, that to-day I am making to you no more than suggestions. Later on, with the experience I hope to gain on the Kybybolite Experimental Farm and on the various farm plots so ably set going by Mr. Colebatch in the South-East, I hope to be able to speak before you with more authority and to be listened to with greater respect.

And here I wish to congratulate Mr. Colebatch on the excellent pioneering work he has carried out during the last five years in this district. As you are all aware, he has quite recently earned well-justified promotion, and I feel certain that the good wishes of South-Eastern farmers will accompany him in his new sphere of work.

### THE SIGNIFICANCE OF FORAGE CROPS IN FARM PRACTICE.

It seems to me that it augurs well for the district that I should have been asked to speak on "Forage Crops" to-day. All the world over special attention to forage crops implies a distinct step forward in general farming practice, and a step which cannot very well be taken until the general economic condition of the country renders it possible. We shall realise the progress implied in the adoption of forage crops in the ordinary routine of farming if we consider the various steps in development usually taken in the settlement of a new country.

In this connection the first stage in land settlement is usually repre-

livestock operations unless he makes amply adequate provision for their upkeep over and above the scanty supplies of available natural pastoral areas.

#### SOURCES FOR THE UPKEEP OF LIVESTOCK OPEN TO FARMERS.

This brings us to the central matter of my address. Roughly speaking, there are three distinct sources upon which livestock should be able to draw for their upkeep on any well-conducted farm:

1. Natural Grazing.
2. Forage Crops.
3. Hand Feeding.

I am of the opinion that anybody wishing to render livestock operations profitable must provide for his livestock adequately along all these three lines.

Natural grazing is not difficult to define; it represents one of two things. It may be the produce of "Temporary Pasture," that is to say, land left out of cultivation and not sown to any particular crop, but merely grazed for a period of one to three years. Later on land of this kind enters again into the ordinary routine of cropping.

On the other hand, natural grazing may be represented by "Permanent Pasture," of which there are such vast areas in County Grey. Now, I do not wish to-day to discuss the question of land that has not as yet been thrown open to farming operations in this district; I have in mind only that land which is actually being farmed under present conditions. And from this point of view I hold that in a district such as this there is only one reason that can justify permanent pasture on a farm, and that is that for various reasons the land cannot be looked upon as *arable*. The land may be too rocky, too steep, too wet, subject to drifting, etc. But, apart from these special accidents, it is in the interests of the State and of the district that every acre of farm land should be, periodically at all events, ploughed and farmed. On farms, therefore, natural grazing would be provided for mainly by what we may term temporary pasture land.

Strictly speaking, it is not very easy to separate very distinctly the feeding of forage crops from hand feeding. Lucerne, for example, is a forage crop, but it is generally hand fed; the same can be said of mangolds and many other true forage crops.

The term "Hand Feeding," on the other hand, is generally reserved for the feeding of concentrated foodstuffs, such as grain and artificial foodstuffs, such as refuse cake, etc.

I have already said that we must depend upon all these three sources of supply for livestock, but very naturally as business men we cannot afford to overlook the expenditure to which we may be put. And in

this connection there is no doubt that natural grazing as practised by the station owner represents the cheapest conceivable method of handling livestock. We have to bear in mind, however, that the carrying capacity of average permanent pasture land is exceedingly small, and if we had to depend upon it exclusively on farmed areas the number of livestock kept would be so small that we might just as well leave them alone for all the benefit they are likely to be to us. I do not forget, however, that the carrying capacity of farm temporary pasture is infinitely greater than that of the permanent pasture of station land.

Forage crops, on the other hand, that are fed off in the field represent probably a cheaper source of upkeep for livestock than ordinary hand feeding. The only expenditure involved is represented by the rent of the land and the cost of seeding and cultivating the crop; there are no harvest expenses. It is perhaps worth noting here that apart from their advantages to livestock the general use of forage crops offers to the farmers many solid indirect advantages. In the first place, the feeding off of forage crops on the land tends to raise the natural fertility of the latter very considerably, and their influence in this direction is very much a factor of their own success. Thus the heavier and the better the forage crop the greater the number of livestock it will be capable of supporting, and the greater the contribution it makes indirectly towards increasing the fertility of the land.

Another indirect advantage that may be claimed for forage crops is that in a measure in combination with main crops they provide for continuous employment on the farm. This, I think, is a matter of very considerable importance. Here in Australia we all experience considerable difficulty in securing suitable farm labor at critical periods of the year. There are, no doubt, many reasons to account for this unfortunate condition of affairs, but among them is the fact that we neglect to provide permanent farm employment from one end of the year to the other. When farming is confined to the raising of one type of crop it is perhaps impossible to do this, but as soon as you introduce on the farm other types of crops, and particularly forage crops, and the livestock which they imply, you tend to render employment fairly continuous on the farm; and this, I think, is an aim which all should have in view.

It would, however, be a mistake to imagine that a farmer keeping livestock must necessarily stop short at forage crops in his attention to their particular requirements. I am perfectly satisfied that no farm adequately stocked can possibly do without a certain amount of hand feeding sometime or other during the course of the year. However careful one may be one is never in a position to depend even on

forage crops from one end of the year to the other, and when they fail us we must, unless we wish to see any falling off in condition, fall back upon hand feeding in some form or other. You recognise this fact readily enough in your treatment of horses and pigs, why then should not cows and sheep be similarly treated? I recognise, of course, that all farmers are not equally sinners in this particular direction; many, however, imagine that they are losing money when they find themselves compelled to feed to cows and sheep foodstuffs which would otherwise be saleable in the open market. And even at the present time it is being whispered that South-Eastern farmers have allowed themselves to be carried away by the high prices that have obtained recently for fodders, and that it is questionable whether the South-East will be able to support its livestock during the coming winter. Another question that may be pointed to in this connection is that farmers frequently put off hand feeding until it is too late; condition has been lost, and hand feeding becomes then an exceedingly costly, if not unprofitable, operation.

In summary, I would say that grazing, forage crops, and hand feeding should go hand in hand on all farms on which livestock are being kept. Nobody suggests that livestock should be hand fed from one end of the year to the other; although I am not at all certain that even this somewhat extravagant treatment might not prove profitable in some special cases. In these matters the farmer must make call on his business instincts, bearing in mind that whatever happens his livestock should at any time of the year be a credit to him.

#### THE POSITION OF FORAGE CROPS IN THE SOUTH-EAST.

There is no doubt that in so far as grazed forage crops are concerned our South-Eastern districts have a tremendous pull over the rest of the State, and that is the pull of climate. It is, indeed, somewhat surprising that greater progress has not been made with these crops in recent years. In our Northern Areas the position is quite different; the local climate is generally fatal to most forage crops usually grown; and we have yet to discover forage crops adapted to these hot dry districts. Already it may be said that we have found one forage crop quite suited to Northern conditions, namely, pease; and in quite a number of instances lucerne is giving very satisfactory results. But what is the position in the more favored South-Eastern country? Here and there we see a few plots of admittedly successful forage crops, but little or nothing of them grown on anything like a large scale. This is certainly not as it should be, and it is to be hoped that in a few year's time we shall notice marked improvement in this direction.

With a view to bringing out this particular point, I have analysed in

Table I. the general distribution of land used for agricultural and pastoral purposes in County Grey as indicated in the 1912-13 statistics.

TABLE I.—*Showing Distribution of Land used for Agricultural and Pastoral Purposes in County Grey, 1912-13.*

| Description.                                                                  | Areas.    | Combined Areas. | Grand Totals. | Percentage of Total Agricultural and Pastoral Areas. |
|-------------------------------------------------------------------------------|-----------|-----------------|---------------|------------------------------------------------------|
|                                                                               | Acres.    | Acres.          | Acres.        | %                                                    |
| <i>I. Land and Crops supplying almost exclusively Livestock Requirements.</i> |           |                 |               |                                                      |
| 1. Land grazed—                                                               |           |                 |               |                                                      |
| Natural Pasture .....                                                         | 1,045,208 |                 |               |                                                      |
| Temporarily grazed ....                                                       | 37,244    |                 |               |                                                      |
| Sown grasses .....                                                            | 16,108    |                 |               |                                                      |
|                                                                               |           | 1,098,560       | —             | 95·20                                                |
| 2. Hay crops—                                                                 |           |                 |               |                                                      |
| Oats .....                                                                    | 14,300    |                 |               |                                                      |
| Wheat .....                                                                   | 1,477     |                 |               |                                                      |
| Barley, rye, &c. ....                                                         | 539       |                 |               |                                                      |
| Lucerne .....                                                                 | 46        |                 |               |                                                      |
|                                                                               |           | 16,362          | —             | 1·42                                                 |
| 3. Oats .....                                                                 | —         | 10,486          | —             | 0·91                                                 |
| 4. Green forage—                                                              |           |                 |               |                                                      |

| 10. Bare fallow .....                                                         |           | 602             | —             | 0·05                                                 |
| Total land not generally supplying livestock.                                 | —         | —               | 26,196        | 2·27                                                 |
| Total pastoral and agricultural areas in County Grey .....                    | —         | —               | 1,153,943     |                                                      |

The following general facts may be noted from this table:—

- (1) 91·97 per cent. of the whole area occupied in County Grey, or 9,197 acres out of every 10,000 acres, are at present being permanently grazed. It is to be assumed, I suppose, that much of this area—1,045,208 acres—will at some time or other be brought under the plough.
- (2) If we divide up the available agricultural and pastoral land in County Grey into two sections, namely, (a) Land and crops

supplying almost exclusively the requirements of livestock; on the one hand, and (b) Land and crops not generally supplying livestock foodstuffs, we notice that the former is represented by 97.73 per cent. of the total area, or 9,773 acres in every 10,000, and the latter by 2.27 per cent. of the total area, or 227 acres in every 10,000. This is indeed an enormous area in one county—1,127,747 acres—to set aside for the upkeep of livestock, and proves, I suppose fairly satisfactorily, the suitability of the district for the purpose

- (3) We notice, further, that in this area set aside for the upkeep of livestock only 253 acres in every 10,000 of the occupied area are specially cropped, whilst 9,520 acres are grazed.
- (4) Finally, out of the general total of 1,127,747 acres more or less wholly given up to the upkeep of livestock, only 2,157 acres are represented by true forage crops, or only 19 acres in every 10,000 acres of the total agricultural and pastoral lands.

#### LIVESTOCK CARRIED BY COUNTY GREY IN 1912.

We must next determine what are the numbers of livestock provided for by this enormous extent of country. These numbers are indicated below in Table II.

TABLE II.—*Showing Total Livestock in County Grey in 1912, together with their Sheep Equivalence.*

| Description. | No. of Head. | Equivalent to Sheep. |
|--------------|--------------|----------------------|
| Cattle ..... | 28,289 ..    | 198,023              |
| Horses ..... | 13,662 ..    | 95,634               |
| Sheep .....  | 523,624 ..   | 523,624              |
| Pigs .....   | 4,869 ..     | 14,607               |

Livestock in County Grey equivalent to ..... 831,888 sheep.

In this Table sheep equivalence has been determined on the assumption that one head of large stock is equivalent to seven sheep, and one pig to three sheep. I quite recognise that standards of this kind have nothing that is absolute in them; their main justification is their convenience for purposes of comparison.

We have already seen in Table I. that 1,127,747 acres were set aside in 1912 in County Grey for the upkeep of livestock. If now we connect with this area the livestock equivalent to 831,888 sheep which County Grey was shown to carry in 1912, this represents an average acre carrying capacity of 0.74 or  $\frac{3}{4}$  of a sheep.

#### DISTRIBUTION OF LAND USED FOR AGRICULTURAL AND PASTORAL PURPOSES IN ENGLAND AND WALES IN 1913.

Now, it is rather important, since we are interested in forage crops, that we should realise what is their influence on the livestock

carrying capacity of other countries in which they are freely availed of. I have, therefore, thought it well to submit to a similar analysis statistical data having reference to the position of England and Wales in this particular direction. This analysis will be found set out in Table III.

TABLE III.—*Showing Distribution of Land used for Agricultural and Pastoral Purposes in England and Wales in 1913.*

| Description.                                                                  | Areas.     | Combined Areas. | Grand Totals. | Percentage of Total Agricultural and Pastoral Areas. |
|-------------------------------------------------------------------------------|------------|-----------------|---------------|------------------------------------------------------|
|                                                                               | Acres.     | Acres.          | Acres.        | %                                                    |

| 8. Celery .....                                                               |            | 5,318           | —             | 0.02                                                 |
| 9. Sugar Beet .....                                                           |            | 4,085           | —             | 0.01                                                 |
| 10. Onions .....                                                              |            | 3,966           | —             | 0.01                                                 |
| 11. Flax .....                                                                |            | 641             | —             | —                                                    |
| 12. Other Crops .....                                                         |            | 98,456          | —             | 0.32                                                 |
| 13. Bare fallow .....                                                         |            | 387,904         | —             | 1.25                                                 |
| Total land not generally supplying livestock foodstuffs .....                 |            | —               | 4,373,382     | 14.14                                                |
| Total agricultural and pastoral land in England and Wales .....               |            |                 | 30,934,648    |                                                      |

We may note the following facts having reference to England and Wales in Table III.

- (1) 85.89 per cent. of the total agricultural and pastoral land, or 8,589 acres in every 10,000, is more or less wholly given up to the upkeep of livestock. This percentage, although still very high, is 12 per cent. lower than is the case in County Grey.
- (2) Permanently grazed and hay land, including mountain and heath land never touched by the plough, is represented by 64.25 per cent. of the total occupied areas, as against 91.97 per cent. for County Grey.
- (3) On the other hand, out of every 10,000 acres of occupied land, 3,545 acres are specially cropped for livestock, whilst only 5,044 acres are uncultivated and grazed. The corresponding figures for County Grey are 253 acres and 9,520 acres respectively.

#### LIVESTOCK IN ENGLAND AND WALES IN 1913.

We must now examine the number of livestock carried in England and Wales on these 26,561,266 acres in 1913. The figures are indicated below, together with their sheep equivalence, in Table IV.

TABLE IV.—*Showing Livestock in England and Wales in 1913, together with their Sheep Equivalence.*

| Description. | No. of Head. |    | Equivalent to Sheep. |
|--------------|--------------|----|----------------------|
| Cattle ..... | 5,716,944    | .. | 40,018,608           |
| Horses ..... | 1,402,146    | .. | 9,815,022            |
| Sheep .....  | 17,130,286   | .. | 17,130,286           |
| Pigs .....   | 2,102,102    | .. | 6,306,306            |

Livestock in England and Wales equivalent to ..... 73,270,222 sheep.

Sheep equivalence has been determined in Table IV. on the lines already indicated for Table II.

We notice that the total number of livestock carried in England and Wales in 1913 was equivalent to 73,270,222 sheep, and if we connect this number with the 26,561,266 acres which have been shown to have provided for their upkeep, we find the average acre-carrying capacity in England and Wales to have been represented by 2.76, or  $2\frac{3}{4}$  sheep, as against  $\frac{1}{4}$  of a sheep from land supporting livestock in County Grey. It must, of course, be added that foreign food materials, such as refuse cake, foreign corn, &c., are more or

less systematically fed to English livestock, and would, therefore, have the effect of reducing somewhat the apparent sheep-supporting capacity of the land indicated above.

#### FORAGE CROPS IN ENGLAND AND WALES.

I believe, however, that this very high livestock carrying capacity of over 26 and a half million acres in England is very largely to be attributed to the very free use that is made in this country of forage crops. I have, therefore, summarised below in Table V. what may be taken to represent the true forage crops of England and Wales.

TABLE V.—*Showing True Forage Crops grown in England and Wales in 1913.*

| Description.                       | Area.     |    | Percentage                                         |
|------------------------------------|-----------|----|----------------------------------------------------|
|                                    |           |    | of Total<br>Agricultural<br>and Pastoral<br>Areas. |
|                                    | Acres.    |    | %                                                  |
| Rotation grasses and clovers ..... | 2,495,832 | .. | 8.05                                               |
| Turnips and swedes .....           | 1,053,395 | .. | 3.41                                               |
| Mangolds .....                     | 419,456   | .. | 1.36                                               |
| Vetches .....                      | 100,945   | .. | 0.33                                               |
| Rape .....                         | 67,395    | .. | 0.22                                               |
| Lucerne ] .....                    | 57,278    | .. | 0.19                                               |
| Cabbages and kales .....           | 55,422    | .. | 0.18                                               |
| Kohl Rabi .....                    | 14,401    | .. | 0.05                                               |
| Carrots .....                      | 10,018    | .. | 0.03                                               |
| Total forage crops .....           | 4,274,142 | .. | 13.82                                              |

Table V. shows how different is the position in England and Wales relatively to forage crops to the position in County Grey. In England and Wales we find true forage crops represented by 13.82 per cent. of the total agricultural and pastoral areas, or 1,382 acres out of every 10,000, as against 19 acres out of every 10,000 in County Grey.

#### DISTRIBUTION OF LAND USED FOR AGRICULTURAL AND PASTORAL PURPOSES IN NEW ZEALAND IN 1912.

You may, perhaps, object to the comparison that I have made between the conditions in County Grey and the conditions in England and Wales. It may very well be argued that, apart altogether from the question of climatic conditions, the economic condition is very far from being the same in the two countries; and that what can be done in one country cannot necessarily be done with advantage in the other. Let us therefore endeavor to ascertain how matters stand in another country, in which the general economic condition is very similar to our own, namely, New Zealand. In Table VI. I have summarised on similar lines what was the distribution of pastoral and agricultural land in New Zealand in 1912.

TABLE VI.—*Showing Distribution of Land used for Agricultural and Pastoral Purposes in New Zealand in 1912.*

| Description.                                                                 | Areas.     | Combined Areas. | Grand Totals. | Percentage of Total Agricultural and Pastoral Areas. % |
|------------------------------------------------------------------------------|------------|-----------------|---------------|--------------------------------------------------------|
|                                                                              | Acres.     | Acres.          | Acres.        |                                                        |
| <i>I. Land supplying almost exclusively Livestock Requirements.</i>          |            |                 |               |                                                        |
| 1. Land grazed—                                                              |            |                 |               |                                                        |

| 7. Hops .....                                                                |            | 653             |               |                                                        |
| 8. Vineyards .....                                                           |            | 780             |               |                                                        |
| 9. Sugar beet .....                                                          |            | 279             | —             | 0.03                                                   |
| 10. Vetches .....                                                            |            | 205             |               |                                                        |
| 11. Other crops .....                                                        |            | 10,739          |               |                                                        |
| 12. Fallow land .....                                                        |            | 209,973         | 753,222       | 1.86                                                   |
| Total land and crops not generally supplying livestock foodstuffs .....      |            | —               | 39,410,664    | 98.12                                                  |
| Total agricultural and pastoral land .....                                   |            | —               | 40,163,896    |                                                        |

We may note the following facts from Table VI. :—

- (1) In New Zealand 98.12 per cent. of the total agricultural and Pastoral area, or 9,812 acres out of every 10,000, is more or

less wholly given up to the upkeep of livestock. This proportion is even higher than we have seen to be the case in County Grey—9,773 acres in every 10,000—and much higher than in England and Wales—8,589 acres in every 10,000.

- (2) In New Zealand permanently grazed land appears to be represented by 94.64 per cent. of the total agricultural and pastoral areas, or 9,464 acres in every 10,000, as against 9,197 acres in County Grey, and 6,425 acres in England and Wales.
- (3) In New Zealand the total area given to the upkeep of livestock is represented by 39,410,664 acres. In this total 348 acres in every 10,000 of the total pastoral and agricultural areas is specially cropped for livestock, as against 3,545 acres in England and Wales, and 253 acres in County Grey.

#### LIVESTOCK IN NEW ZEALAND IN 1912.

We shall now proceed to examine the number of livestock occupying this vast area of country in 1912. All data concerning them, together with their sheep equivalents, are shown below in Table VII.

TABLE VII.—*Showing Livestock in New Zealand in 1912, together with their Sheep Equivalence.*

| Description.                                 | No. of Head. | Equivalent to Sheep. |
|----------------------------------------------|--------------|----------------------|
| Cattle .....                                 | 2,020,171    | 14,141,197           |
| Horses .....                                 | 404,688      | 2,832,816            |
| Sheep .....                                  | 24,191,810   | 24,191,810           |
| Pigs .....                                   | 348,754      | 1,046,262            |
| Livestock in New Zealand equivalent to ..... |              | 42,212,085 sheep.    |

As in previous cases, sheep equivalence in Table VII. has been determined on the assumption that one head of large stock is equivalent to seven sheep, and one pig to three sheep. We note, therefore, that these 39,410,664 acres provided for the upkeep of livestock equivalent to 42,212,085 sheep; this represents an average acre-carrying capacity of 1.07 sheep, as against 0.74 sheep in County Grey, and 2.76 sheep in England and Wales. It follows, therefore, that whilst the stock position in New Zealand is certainly better than in County Grey, it still lags a long way behind England and Wales.

#### FORAGE CROPS IN NEW ZEALAND.

This relative inferiority of New Zealand may perhaps be attributed to the fact that although she has taken up forage crops to a certain extent, it is nothing like the same proportion that obtains in England and Wales. I have summarised below in Table VIII. the chief forage crops grown by New Zealand in 1912.

TABLE VIII.—*Showing true Forage crops grown in New Zealand in 1912.*

| Description.                    | Area.   |    | Percentage of Total              |
|---------------------------------|---------|----|----------------------------------|
|                                 |         |    | Agricultural and Pastoral Areas. |
|                                 | Acres.  |    | %                                |
| Turnips .....                   | 450,059 | .. | 1.12                             |
| Rape and kale .....             | 208,057 | .. | 0.52                             |
| Green forage, cereals, &c. .... | 15,914  | .. | 0.04                             |
| Mangolds .....                  | 14,082  | .. | 0.04                             |
| Carrots .....                   | 2,363   | .. | 0.01                             |
| Total forage crops .....        | 691,375 | .. | 1.73                             |

We note, therefore, that in 1912 New Zealand carried 691,375 acres of forage crops representing 1.73 per cent. of the total agricultural and pastoral area. It should be added that sown grasses and clovers have not been included in this total, because there is nothing to show in the statistics that these do not form part of the permanent grazing areas, as distinct from the rotation grasses of England. In New Zealand, therefore, out of every 10,000 acres of the occupied areas, 173 were under forage crops, as against 19 in County Grey, and 1,382 in England and Wales. These figures, therefore, will perhaps serve to account for the superiority of the livestock position in New Zealand over the position in County Grey; and on the other hand, the inferiority of the livestock position in New Zealand relative to that of England and Wales.

#### SUMMARY OF COMPARISON OF CONDITIONS IN COUNTY GREY, IN ENGLAND AND WALES, AND IN NEW ZEALAND.

Finally, in Table IX., I have summarised the salient differences to which attention has already been drawn in the cases of County Grey, England and Wales, and New Zealand.

TABLE IX.—*Summarising Comparison of County Grey with New Zealand, and England and Wales.*

| Description.                                                                                         | County Grey. | New Zealand. | England and Wales. |
|------------------------------------------------------------------------------------------------------|--------------|--------------|--------------------|
|                                                                                                      | Acres.       | Acres.       | Acres.             |
| Total agricultural and pastoral areas .....                                                          | 1,153,943    | 40,163,886   | 30,934,648         |
| Area supporting almost exclusively livestock ..                                                      | 1,127,747    | 39,410,664   | 26,561,266         |
| Percentage of agricultural and pastoral areas supporting livestock .....                             | 97.73%       | 98.12%       | 85.89%             |
| Crops specially grown for livestock .....                                                            | 29,187       | 1,398,236    | 11,959,192         |
| Percentage of agricultural and pastoral areas of crops specially grown for livestock .....           | 235          | 348          | 3,545              |
| Area under forage crops .....                                                                        | 2,157        | 691,375      | 4,274,142          |
| Percentage of agricultural and pastoral areas under forage crops .....                               | 0.19%        | 1.73%        | 13.82%             |
| Total livestock carried expressed as their equivalent in sheep .....                                 | 831,888      | 42,212,085   | 73,270,222         |
| Livestock carried on area supporting livestock expressed in their equivalent as sheep per acre ..... | 0.74%        | 1.07%        | 2.76%              |

## GENERAL CONCLUSIONS FROM STATISTICAL DATA.

In a general way I think we may conclude that whilst the livestock position is good in England and Wales, it might be improved upon considerably in County Grey. If we admit the suitability of the South-East in general, and County Grey in particular, to livestock operations—and this is hardly likely to be disputed—we may assume that anything tending towards increasing the average livestock-carrying capacity of the country will tend to bring about corresponding increase in wealth to the district and to the State. If we take into consideration what is happening in England and Wales, on the one hand, and to a less degree in New Zealand, on the other, we may conclude that the carrying capacity of the South-East could be very materially increased (1) by heavy dependence on forage crops, and (2) by judicious handfeeding. It is perhaps perfectly true that general climatic conditions are more favorable to the general growth of forage crops both in Great Britain and New Zealand than is the case in the South-East. Nevertheless, it has been shown over and over again, on a small scale, it is true, that quite a number of forage crops succeed very well in the South-East in most seasons. And what has been done on a small scale can be done on a large one, providing the same amount of care and attention is given to the crops. There is no doubt that one cause of failure with many forage crops is that farmers are apt to think that they call for no particular tillage. This is very far from being the case. Most forage crops call for a good deal of cultivation during their period of growth; they are in this connection very largely fallow crops—that is to say, crops cleaning the land and preparing the way for other crops which cannot be so treated. On the whole, unless forage crops are to receive reasonable and careful treatment, it would probably be more profitable to leave them alone altogether.

The question of the action of local economic conditions on forage crops is, I think, settled by the position of New Zealand. If, for example, independently of the question of climatic conditions, New Zealand can grow mangolds to advantage, there is no apparent reason why the same could not be done in the South-East.

## IMPORTANCE OF FORAGE CROPS ON THE POORER CLASS OF LAND IN THE SOUTH-EAST.

We all know that the natural fertility of the land in the immediate neighborhood of Mount Gambier, and on adjoining volcanic areas, is very great. It must be admitted, however, that much of the land in the South-East is only of very moderate fertility, and some of it very light and very poor in quality. There is not the slightest doubt

that much of this land can be converted into very fair agricultural land. It is only a question of time and intelligent practice. The cheapest and the most effective method of raising the natural fertility of the land is to cause livestock to graze over it; and no doubt the few sheep that are at present allowed to graze the pastoral areas are already doing something in that direction; but their numbers are so small, and their influence so limited, that it will take centuries to secure anything like appreciable results. On the other hand, forage crops, if well grown, will enable the farmer to gather together on these poor light lands large numbers of livestock. A practice of this kind continued over a number of years will in the long run have the effect of transforming relatively poor land into land of considerable agricultural value. It seems to me, therefore, that this indirect action of forage crops would alone justify land owners in the South-East in availing themselves freely of these crops.

#### POSITION OF FORAGE CROPS IN GENERAL ROTATION OF FARM

Whenever new types of crops are introduced on a farm it is very essential that they should not disturb to any degree other main crops that have long been grown there. And unquestionably if forage crops are new to us, when we first take them up we shall have to consider carefully what is to be their relationship to other crops already grown on the farm. Nobody imagines, for example, that forage crops, or, for that matter, any type of crop, can be scattered indiscriminately over a farm. Success in any line of life implies, as a rule, order and organisation; and both order and organisation must preside over the distribution of farm crops. The essential is that the various crops follow one another in orderly succession on the same land; not hindering one another, but the rather, wherever possible, helping and completing one another. This represents roughly the rudiments of what is known as rotation.

In the first place, general experience shows that one and the same crop cannot be made to grow year after year on the same land with any degree of success; crops different in kind must, therefore, succeed one another year after year. It should not be imagined, however, that it is a matter of indifference as to the position given in this succession to any particular crop. And in this connection the position given to a forage crop must depend much on its type and the general treatment to which it may be subjected. Let us examine a few examples.

Many forage crops are leguminous, as, for example, the various clovers, peas, beans, vetches, &c. We know that all leguminous crops can be made to precede the cereals with great advantage;

hence, should we be growing any one of the above-named crops, as much as possible they should be followed by barley, oats, or particularly wheat.

Forage root crops are not so easily disposed of; generally speaking they are placed at the head of rotation, and heavily dressed with farmyard manure. This would be the treatment best suited to mangolds and turnips, for example. Mangolds are as a rule left too long in the ground to be of much advantage to wheat; they leave the land too loose and open for the wheat crop at seeding time. Consequently, although wheat is frequently grown after mangolds, both oats and barley are to be preferred in this connection to wheat.

Turnips, when winter fed, present even greater difficulties for wheat. As a rule they can only be followed by a cereal that can be sown very late in the season, like barley.

Examples of this kind might be multiplied indefinitely; it is sufficient, however, that we note here that new forage crops introduced on the farm must always be carefully studied as to their probable influence on existing crops.

#### TYPES OF FORAGE CROPS SUGGESTED FOR THE SOUTH-EAST.

I am now compelled to make some definite reference to the types of crops that I imagine might prove best adapted to the South-East. In this connection I must repeat that I have hardly enough local experience to prove an altogether safe guide. For the present, I must depend upon the views of others, although in a few years' time I anticipate having at my disposal definite data which will set at rest any difficulties I may at present feel.

It seems to me that when any attempt is made to introduce forage crops into a new district or country the first essential is to ascertain the time of the year when these forage crops are likely to be of greatest use. For example, in a general way, I suppose we might divide up forage crops into three sections:—(1) Forage crops that are mainly summer grown, but which do not become available until the winter months. (2) Forage crops that are chiefly winter and spring grown, and become available in spring and the early summer. (3) Forage crops that are mainly spring and summer grown, and become available towards midsummer.

As a matter of general experience it would seem that a forage crop would be most useful which became available when natural pasture was most lacking. I am not able to speak for the South-East with any degree of certainty; but it appears to me that natural feed is, as a rule, scantiest during the cold winter months of the

year. Hence I conclude that for the South-East those forage crops are likely to be most useful which, whilst making chiefly summer growth, need not be fed off until the winter months of the year. At the same time, I quite recognise that in many circumstances forage crops becoming available in spring and in summer are exceedingly useful; they must, however, occupy a position of secondary importance relatively to the winter-consumed forage crops.

I shall now proceed to pass in review the chief types of forage crops that appear to me likely to prove most useful to your district.

#### *Turnips and Swedes.*

Turnips, as we have seen, form the chief forage crop grown both in Britain and in New Zealand, and so great is their value to the country in which they can be grown to advantage that I wish very much that I could whole-heartedly recommend them to the South-East. There is no portion of South Australia in which climatic conditions approach more closely those of these two countries than is the case in the South-East; the trouble is, however, as to whether this similarity in conditions is sufficiently close for practical purposes. The field turnip is a crop calling for rather moist summer conditions that are fairly typical of England; this peculiarity of the turnip crop has hindered its spread over the Continent of Europe, and may neutralise its value in the South-East. Its importance, however, is so great that I do not think that it should be set aside altogether without a very careful investigation into its local adaptability.

Field turnips have been in use in England on a large scale since 1730, and in order to convey to you some idea of their value as a field crop I shall quote to you a short paragraph which was written some hundred years ago:—"A new source of agricultural wealth was discovered in turnips, which, as their important qualities became known, excited in many of their early cultivators much of the same sort of enthusiasm as they did in Lord Monboddo, who, on returning home from circuit, went to look at a field of them by candle light. Turnips gradually replaced the old bare fallows, filled the cattle mangers with food in winter, and when fed off on the light soils by sheep, consolidated, while they warmed them, and prepared the way for corn crops on wastes that had hitherto only carried rabbits or geese."

Now we have in the South-East thousands of acres, which, if they do not carry geese, carry rabbits in abundance. Without a doubt land of this character can be rendered profitable if only turnips can be made to succeed in our midst. I have been told that turnips

have been tried and found wanting in the South-East; I am not quite clear as to the reason of this failure. It cannot very well be for economic reasons, since we find the crop succeeding very well in New Zealand. Possibly the climate, or, more probably, the special season in which the crop was tested, is to blame. In matters of this importance it will be wrong calmly to submit to the verdict of a single season; and, so far as I am concerned, turnips will need to fail a good many times before I shall give them up altogether. And if we have to give up the white turnip, we may still be able to fall back upon the Swede, which is far more resistant to summer drought, and on the whole better feeding value.

Turnips and Swedes are essentially suited to the lighter types of soil which are so abundantly represented in the South-Eastern Counties. They do not thrive, however, as a rule in soils which are at all deficient in lime; hence if we are to make any use of them we must lime the soil on the lines so persistently recommended to you by Mr. Colebatch. If you have any stable manure available you cannot put it to better advantage than in dressing with it the land which is to carry turnips. The seed itself should be sown with a moderate dressing of phosphatic manures.

There is one difficulty connected with the growing of turnips which can only be settled by local experiment, and that is the most suitable time of the year to sow the crop. If turnips are sown too early in the spring they are apt to run away to seed in the course of the first summer, a fact which is fatal to their value as winter forage; whilst if they are sown too late, they may just miss the moisture essential to good germination and to early growth.

If the seed is sown through the manure openings in mixture, say, with bonedust, it should be sown at the rate of 2lbs. to 3lbs. to the acre, in rows 24in. to 30in. apart. This practice involves a certain amount of hand thinning, so as to leave the roots about 8in. to 10in. apart in the rows. This work may be avoided, however, by adopting the New Zealand practice of sowing 10ozs. to 12ozs. of seed to the acre through the small seed drill attachment, which drops the seed, grain by grain, at suitable distances.

The turnip crop will generally be sown on a cereal stubble, and the crop, therefore, will be tolerably weedy. This means that if we are to get good growth turnips must be horse-hoed during the growing season. They form, therefore, a useful fallow crop, cleaning the land for the crop that follows. There is no difficulty in the handling of the crop in the winter; sheep are generally folded on the turnips, and when accustomed to them eat them out completely.

It is generally reckoned that a good crop of turnips should carry about 400 sheep to the acre for a week, that is to say an equivalent of seven to eight sheep to the acre per annum.

### *Kales and Cabbages.*

The kales and cabbages represent crops which one can recommend with greater confidence in the South-East than is possible in the case of turnips. Kale, at all events, has already been grown very successfully in various parts of the South-East, and in favorable seasons has given very satisfactory results even in the Lower North. Mr. Colebatch has had every reason to be satisfied with kale at Kybybolite and at Glencoe; indeed, so generally recognised is the value of this forage crop in the South-East, that it is somewhat surprising that greater advantage has not as yet been taken of it.

Under this heading we may conveniently group together quite a number of forage crops, all of which call for identical treatment, namely:—Thousand-headed kale, the crop which is best known both here and in the Lower North; probably of all it is the most useful for sheep. Jersey tree kale, a larger growing type of kale, which, on account of its size, is generally dibbled out, and the leaves of which it is customary to strip. This crop has been known to yield as much as 40 tons to 50 tons of green stuff to the acre in the course of 18 months; unfortunately the hand labor involved is rather too great for its use on anything like a large scale under our conditions. Cattle cabbage, of the drumhead type, and forming a heart like the well-known vegetable. This is an excellent forage crop, yielding very abundantly under favorable conditions, and well worth testing locally. Marrow-stem cabbages, or what are sometimes known as Chou Moellier. These cabbages have been tried in the South-East with, I believe, satisfactory results. Kohl Rabi, or the turnip cabbage, the only cabbage that is said not to taint milk, although I am not prepared to guarantee this fact.

All these kales and cabbages are, in my opinion, well worth testing in the South-East; they admit of repeated grazing, and represent in consequence even heavier feeding value than a good turnip crop. They are also to a greater extent drought-resistant. They may be used for late summer grazing, or be kept back for winter forage purposes. At a pinch they will supply feed for two years in succession; the second year's growth, however, is never equal to that of the first, and, as a rule, the land can be put to better advantage under some other crop.

The kales and cabbages thrive best in heavy land, and generally benefit from a dressing of farmyard manure if the latter is available.

Like turnips, they can follow a cereal crop, the stubbles of which can be broken in winter and got ready for seeding by early spring. The seed may be drilled in with bonedust through the manure openings, at the rate of 1lb. to the acre, in rows 24in. to 32in. apart; or else with the aid of the small seed attachment already referred to. If the kale is to make good growth the land must be kept well worked during its growing season.

#### *Rape.*

One of the best of the forage crops for sheep. I know that there are local objections to rape because of its liability to aphids. This, however, represents as a rule an accident accompanying dry seasons; and, until further informed by personal experience, I cannot agree that it constitutes an objection sufficiently great to set aside altogether so valuable a crop as rape. Nobody would ever recommend farmers to confine their forage crops to one special type; suitable areas of several different kinds should always be grown, so as to make ample provision for any failure that may arise. And in my opinion, rape should always take its place, at all events, as a fair percentage of the area under forage crop on any farm on which sheep are kept.

Rape is not so essentially a winter-fed forage crop as turnips; it can be sown in spring or in the early autumn, and should be fed down fairly consistently throughout its growing period. Hence it does not call for the after tillage so necessary with most other forage crops. It is best suited to medium loams, and should be sown at the rate of 4lbs. to 5lbs. of seed to the acre, in mixture with manure.

#### *White Mustard.*

White mustard is a forage crop that can be grown with great advantage as a catch crop, coming, say, between a cereal crop and some other spring-sown crop. It makes exceedingly rapid growth during the winter months, and can be utilised with great advantage whenever there is any danger of shortage of winter feed. It is most at home on comparatively fertile land, but will, on the whole, do fairly well almost anywhere. It should be drilled in at the rate of from 4lbs. to 5lbs. of seed to the acre.

#### *Mangolds.*

Wherever they can be grown to advantage, mangolds represent one of the best forage crops known. Good average yields of this crop may be taken to be represented by 25 tons to 30 tons of roots to the acre; under favorable conditions, however, very much heavier crops have been recorded. Unfortunately this crop labors under

rather heavy disabilities, namely, it is apt to involve a rather heavy amount of hand labor. Thus, in the first place, hand thinning out of the plants cannot be avoided, as is the case with turnips. With mangolds it is customary to sow pods, and not seeds; hence two or three plants spring up together, and, unless they are singled out by hand, they hinder one another's development. Secondly, the mangold cannot with advantage be fed on the spot in the field; it must in the first place be pulled and stored away to ripen, very much as is the case with apples and pears. In other words, it is not good feeding value until it has ripened off in this way. This process involves a good deal of hand labor, as the roots must be handled very carefully if one wishes to avoid their rotting away in the heap. At a pinch, it is true, the ripening process might be allowed to take place in the land, but for the fact that the roots suffer much from the action of frosts.

It appears to me that these two objections may prove insuperable in so far as the profitable growing of mangolds in this district is concerned. But were it not for these objections, I do not know of any forage crop better suited to local conditions. Mangolds are far more drought-resistant than either turnips or Swedes, and adapt themselves to almost any type of soil that is sufficiently deep for their root development. Heavy yields, of course, are secured only in fertile soil, or under the influence of heavy dressings of farmyard manure. The land that is to receive mangolds should always be deeply cultivated in the winter, and reduced to a good condition of tilth early in spring. With mangolds it is highly advantageous that they be sown on a comparatively clean and weed free land: otherwise they call for rather extensive horse-hoeing. The seed should be sown as early in the spring as circumstances permit of; to a very large extent the importance of the yield may be said to depend very largely on the date of seeding. The mangold is a slow-developing root, which is always checked by autumn low temperature; hence the earlier the seeding date the heavier the yield of mangolds. The seed is sown in drills at the rate of 4lbs. to 6lbs. to the acre, and in rows 24in. to 30in. apart, so as to permit of the necessary horse-hoeing.

Mangold seed is apt to rise very irregularly; this may be due either to too deep seeding, or else to defective germination. Hence seed should always be tested before sowing, and a good seed should show a germination percentage of at least 120. The roots should be hand pulled, so as to place them finally 8in. to 9in. apart, and the land between the rows kept loose and free from weeds throughout the growing season.

*Clovers.*

There are several very useful cultivated clovers. Most of them, however, enter into grazing mixtures forming temporary or permanent pasture; and as such do not concern us to-day. A few clovers, however, may be taken to be characteristic forage crops, occupying the land only from 12 months to 18 months, and preparing the way for other farm crops. Of such is the common red clover, or the broad-leaved clover of the English rotations. This clover is generally sown in a spring cereal, usually barley. It grows up in the shelter of the barley crop, but does not actually become available until the following year, when it may be cut for green forage or converted into hay. It always supplies an abundant grazing aftermath. In English practice the red clover is usually followed by autumn wheat sown in the same year. I am not aware as to the extent this clover may have been tested in the South-East; but I am satisfied it is well worth a trial. It cannot be said, however, to thrive on poor light land; it is generally most at home in fertile localities, and on soils that are fairly firm, and of at least medium consistency. It should be added that red clover is frequently grown with advantage in conjunction with rye grass and other grasses.

Crimson or Italian clover is far less valuable as a forage crop than red clover, but it is far hardier; hence its chances of success in the South-East are probably greater than that of the former. It should be sown in early autumn, and may be depended upon to supply an abundant spring forage, which may either be grazed or converted into hay; it must be admitted, however, that the hay is generally rather hard and poor in quality. The other clovers, such as white or Dutch clover, Alsike clover, &c., are chiefly adapted to land which is left out of cultivation for quite a number of years.

*Lucerne.*

Perhaps I should not have referred to lucerne to-day. It is so manifestly a forage crop occupying the land for several years that it can hardly be assumed to enter into ordinary cropping rotations. I am not altogether sure, however, that it is not customary to overstate the length of life of a lucerne field. I am of the opinion that under favorable conditions an average lucerne field begins to decline between its fifth and its tenth year. And it then becomes a question as to whether the lucerne crop is not cumbering the ground, and whether it could not be replaced with great advantage by some other crop. This is the position for lucerne which is carefully grown and regularly cut for green forage or hay purposes. But lucerne

can be utilised very advantageously under very different treatment, as many of us have learnt in the North; and I see no reason why our results should not be bettered in the South-East. Lucerne is broadcasted over a hay crop at the rate of 8lbs. to 10lbs. to the acre, and lightly rolled in; and later on, if the lucerne stand is satisfactory, it will yield exceedingly good summer feeding for a period of at least three years.

I understand that Mr. Colebatch has been unsuccessful with lucerne sown in this way at Kybybolite, and I believe that he has tested both spring and autumn sowing. For the present I shall look upon his lack of success as purely accidental, and propose giving to lucerne more extended trials than it has received as yet.

It is perhaps worth noting that the success of lucerne is sometimes dependent on at least two outside factors, which are sometimes unfavorable in our soils. One of these factors is an inadequate supply of lime; hence soils lacking lime should be carefully limed before lucerne is placed upon them. The second factor is the presence of bacteria, which develop on the roots of the plant. Bacteria of this kind are generally more or less ubiquitous; but if thought to be absent it would be sufficient to secure some old soil from a lucerne field, and to drill it rapidly over the land; probably the seed itself could be mixed previously with the soil.

#### *Sorghum and Millets.*

Experience has shown that both sorghums and millets thrive exceedingly well in the South-East, and where summer green forage crops are required they cannot be too highly recommended. They are essentially adapted to the lighter types of soils and those of medium consistency. They are spring sown, and usually come in for use during the summer months. It should be noted, however, that late-sown sorghum crops, after forming and ripening their seed, will retain their full color and full succulence throughout the winter months if left standing in the field. Sorghums, therefore, may be treated as forage crops, becoming available in winter, if necessity to do so should ever arise.

#### *Rye Grass.*

There are two typical rye grasses, namely, perennial rye and Italian rye. Perennial rye is suited chiefly to temporary and particularly to permanent pastures. Italian rye, on the other hand, is an annual, or, at the outmost, a bi-annual crop; hence it may be looked upon as a typical forage crop, to be used as green forage, for hay, or simply for grazing purposes. Italian rye may be sown either alone on specially prepared land, or else in a cereal crop, as

is the case with red clover. It is a forage crop making extremely strong growth, and which can be safely recommended in these districts, where it is, I understand, already favorably known.

### *Pumpkins and Pie Melons.*

Pumpkins have been said to be grown very successfully for sheep in some portions of New Zealand. Under suitable conditions the acre weight represented in a good crop of pumpkins is very considerable; and since, if necessary, pumpkins can be stored away until required, they should commend themselves as a crop to those who are likely to be short of winter feed. Sheep will take to them readily enough if they are broken open with a spade or an axe. Pie melons, although less nutritious, are also very useful for forage purposes, particularly in sandy localities. I have hand-fed them to sheep at Roseworthy in years in which there was practically no winter feed. We found that the pie melons went furthest if they were put through a turnip slicer.

### SUMMARY AND REVIEW.

Let us now endeavor briefly to summarise the position of forage crops in the South-East. We have noticed how vast was the area in the South-East given up more or less to livestock. We have seen, too, that on the whole the livestock-carrying capacity of this area is far lower than is the case in many other countries. A comparison of the results in other countries, such as Great Britain and New Zealand, would lead us to infer that not only would the livestock-carrying capacity of the South-East be considerably raised, but also its general wealth-producing capacity, if greater attention could be paid to forage crops, combined with judiciously-timed hand-feeding.

I have drawn attention to some of the forage crops that appear to me suitable to your districts. I may have overlooked some which have an equal claim on our attention; and I may possibly have overestimated the claims of others. Among the most likely forage crops I think might be quoted the kales and cabbages, rape, and sorghums. I trust, however, that circumstances will be such that all will receive a fair trial.

In the discussion which followed the delivery of the above address, Mr. S. Ockley (Penola) congratulated the Director upon his able treatment of a subject that was of vital importance to the district. In new ground of an inferior character—yacca land—he had found that maize would make remarkable growth in the summer. The

cost of seed and manure was 2s. 3d. per acre, and the return was 30cwts. to the acre. He saved the expense of cutting by turning on the stock, and then he invariably got a good follow-on crop of oats.

Mr. F. Coleman said the time must come when producers would be forced to grow more fodder. At the Islington Sewage Farm *panicum crusgalli major*, a valuable grass, was well established, and £10 per acre was paid by lessees for the privilege of cutting it for stock. It had not been sown, but had been distributed by wind or water.

The Minister asked, seeing that before long they would have a port with freezing works, whether it would not pay them to produce more stock to meet the world-wide demand for meat. The point they had to determine was whether it would pay them better than other lines.

Mr. C. E. Birks said peas and barley were useful forage crops. There were thousands of acres of land in the State which would grow good forage crops the first year they were cleared.

### GRADING AND MARKING OF FRUIT FOR OVERSEA MARKETS.

Reporting to the Minister of Agriculture, under date London, March 12th, the Trade Commissioner writes:—"American and Canadian shippers are experiencing a bad selling season. Fruit of excellent quality is realising from 7s. 6d. to 10s. per case, and shipments and stocks are reported to be extremely heavy. I have inspected quite a number of their shipments, and am particularly impressed by the uniformity of their grading and freedom from disease. They have adopted an excellent method of marking by means of colored paper labels pasted on the ends of the cases, which presents no difficulty in identifying marks, and certainly saves considerable time and worry and dockers' charge. I am of the opinion that this system will be well worth experimenting with in South Australia, and under separate cover I am sending several samples of case ends, which will illustrate the methods adopted." These samples can be seen in the Produce Department, Victoria Square, Adelaide.

## BLOOD WORMS.

By F. E. PLACE, B.V.Sc., M.R.C.V.S., Government Veterinary Lecturer.

So many inquiries have reached the Veterinary Lecturer on the subject of blood worms, and the treatment of animals infested with them, that it has become necessary to issue the following notes on the subject to supplement the information already available, and to prevent the endless reiteration of information in replies to correspondents as to symptoms and treatment.

The name blood worm, like most general appellations, is useful but somewhat misleading, and the implied redness of the worm is by no means always present; on the other hand, other red worms suffer in reputation on account of it, for the redness of the little wrigglers so often found in troughs and the like is not due to horses' blood, and, scientifically, they are not worms, but larvæ of various winged insects, such as gnats, and if a horse drinks them in he will digest them, and they will do him no harm. There are many branches of the blood worm family, some score or more, but practically only three sorts affect horses in South Australia. These are known to science under various names, but the one most commonly used is *Sclerostomata*, or hard-mouthed ones, a division of the class *Strongylidae*, or thin round worms, so that to the layman they are thin round worms with hard mouths; the man of science further labels them as *Sclerostomum armatum*, or *equinum*, that is the armed worm or horse worm, and this is commonly spoken of as the big blood worm, which is from 20 to 30 millimetres long, and sometimes much longer (roughly, 25 millimetres go to an inch), and about the size of a grass stem in circumference; they are sometimes called palisade worms, because they look like little round battens. As a rule they are not red, but a dirty grey, unless they have just had a meal of blood, which will then show red through their thin skin.

The second in the family is called *Sclerostomum tetracanthum*, or the hard-mouthed one, with four spikes, and is much smaller than the last, so is often called the small blood worm; it is usually greyish-white in color, but is much more frequently noticed as a red worm, on account of the blood shining through the thin coat. It is from 10 to 15 millimetres long, and the thickness of sewing thread or fine string.

The third is less common than the other two, and is smaller in size as a rule, though often giants of the race may be found; it is usually yellowish-white in colour, but red from contained blood, and is named *Sclerostomum edentatum*, or toothless one of the hard mouth, and is seldom found outside blood vessels.

Scientists having identified the beasts and duly christened them, then begin to differ as to what they are and what they do and where they will be found; hence the different opinions that one hears about them; but the following are facts, and interesting ones, and are more or less common to the three sorts, namely, that they may be found in the large bowels of the horse and in the blood vessels in the neighborhood, holding on to the lining of the bowel or vessel by their hard mouths, causing little prominences varying from a pin-head to a millet seed in size, and sometimes much larger, in which case an embryo worm will be found in the tumor, which is known to knackers as a "fat stone," and may very frequently be found connected with the lymphatic glands or kernels on the mesentery or caulfat. Some investigators look on these as similar to the queen bee in a hive, others deny such a function; but it is certain that the usual mode of reproduction takes place as follows:—The worms in the bowels give off eggs, some 30,000 per female, which are passed in the horse's dung, where, if conditions of moisture are favorable, they will hatch out in a few days, while on the other hand, they may remain dormant for many months, even years. The embryos which hatch out are  $\frac{1}{4}$  mm. or less in length, and, being microscopic, are taken into the horse in food and water in large numbers, and as millions are often found in a horse, it follows that millions are thus swallowed, and on account of their smallness readily pass through the coats of the bowel into the neighboring blood vessels, where they grow, and finally bore their way back to the bowel, become differentiated as to sex, copulate, and pass eggs as before, and in the case of the big blood worm, may almost invariably be found hanging on to the inner coat of the caecum or large water gut, where also, and in the large paunch-like gut, or four-folded colon, may be found the small blood worm in thousands; while the third sort will mostly be found in the blood vessels of the kidneys.

Now when they wander from the bowels into the blood vessels around them their track may often be followed by the jelly-like substance and bubbles of gas that are found on the upper surface of the bowel, and when they have decided on the spot where they are going to stay awhile, the result of their digging their noses into the glistening lining of the vessel is an aneurism, or swelling of the artery, generally about the size of a walnut, often no bigger than

a pea, and sometimes as big as a baby's head. The swelling is generally radish-shaped; the outer wall of the vessel is thickened and hardened and confused with the connective tissue around it, the middle or muscular coat of the vessel is always thickened, while normally about a millimetre in thickness, it increases to 20mm. or 25mm., and the muscle fibres degenerate. The inner coat, usually bright and shiny, is always altered, perhaps only a little thickened and milky white, or ulcerated and greatly thickened and hard as stone or bone.

Within this aneurism there is a whitish-yellow, jelly-like fibrinous deposit, a thrombus, attached to the inner coat of the vessel, though perhaps only partially so, extending both in front and behind the aneurism, sometimes for a long distance, and is due directly to the action of worms. These average about a dozen, and may be hundreds; when they are present the symptoms are acute, when absent chronic. The young worms are rose-tinted, stuck in the jelly, with their heads and tails in the blood stream, their mouths often glued to the coats of the vessel.

Now, mechanically, alone such a condition of things is fraught with danger; the aneurism, subjected to a strain such as rolling or pulling, may burst, and the animal bleed to death internally; but more commonly fragments of the thrombus break off, and block smaller vessels, causing embolism, or choking of the artery, and a sudden change in the blood supply of the part occurs, resulting in paralysis of one or more sections of the digestive tube, the secretions and movements of which are suspended. When this occurs in the main artery supplying the bowels, the great mesenteric, the bowel changes from a pale to a dark red color, its lining, the mucous membrane, is swollen, there are streaks and spots of dark-colored blood, jelly-like swellings, and often the organ is considerably enlarged, the appearances of what is commonly called blood colic in South Australia. Often difficulty is experienced in finding the embolism, because of the many ramifications of the blood vessels, while such circulation disturbances of the bowel cause a local paralysis, with stagnation, free fermentation of the contents, and painful griping, often resulting in bursting of the bowel.

The effects of the worm aneurism vary very considerably in relation to its situation. It may be in the great mesentery artery, and diminish the supply of blood to the bowels, generally resulting in chronic indigestion, especially when a clotting in a branch entirely deprives a portion of the bowel of its blood supply, the difficulty being gradually got over by other branches of the artery taking on the work of the blocked one. But, as very frequently happens, the

right branch of the great mesenteric becomes completely blocked, and then the great water gut, the cæcum, is deprived of its blood supply, and acute stoppage, or colic, quickly ends the horse's life. The large four-folded colon, deriving its blood supply from two sources, seldom has them both blocked at one time, so it manages to get on with its work after a fashion.

Death results from any one of several mechanical causes, such as failure of lungs or heart to act on account of pressure on the diaphragm by the distended bowels, congestion of the brain on account of the blocking of big vessels in the belly; but modern investigation has shown that the infestation by these worms results in a breaking-down of the blood which is utilised by them and passed out as excrement in a useless condition, and that this worm digestion results in the formation of substances which are actively poisonous to the horse, and responsible for many of the symptoms observed.

What are the symptoms of blood worms?—a question asked in scores of letters and at nearly every meeting. The answer is disappointing. There are no definite symptoms except the production of the worms themselves, and if these have been killed by medication, they are digestible and digested, and not to be seen in the dung.

If an aneurism has burst the symptoms are distinct. There has been an accident or severe exertion, the animal crouches or sits on its haunches, knuckles over at the fetlocks, and falls as if paralysed; the pulse is thready, and the whites of the eyes very pale, severe and prolonged struggles at the point of death.

The general symptoms are:—Harsh and staring coat, loss of form and vigor, stiffness of the hindquarters, difficulty and pain in passing urine, but frequent attempts to do so, arching of the back, pasty swelling of limbs, lips, and belly, cramp and paralysis.

In less acute cases:—Variation of appetite, increased thirst, and dung seldom passed, the pellets small and dry, becoming softer and pasty, stinking, and sometimes bloodstained. The urine is acid, and has a thick sediment; the pulse is small and quick.

The attacks of colic are worse after feeding, and as a rule are not very severe; the horse is ill for a long time, and lies down for hours together, looking at his side and groaning occasionally, then getting up and seeming better, feeding and getting worse, and so on, till fed only on straw thatch, he concludes that life is not worth living and departs. To find out if these worms are present, fill a bucket one-third with dung recently passed and fill up with water and stir up well and allow to settle; skim off the scum, and decant off the

liquor; take a little of the sediment and spread on a dark surface, such as a bit of American cloth or oilskin, and search carefully for the worms. Probably they will not be found at first or second shot, but will appear if the proceeding is repeated often enough.

### TREATMENT.

Treatment.—Fire and water. It is heresy in these days of the gospel of conservation of fodder to preach the burning of stubble, but such a proceeding very effectually fries the worm eggs. Water.—Chief Inspectors of Stock even unto the third and fourth generation have lifted up their voices against the danger of the dam side and the crumbling creek bank, and have been but voices crying in the wilderness, though where water is lifted the simplest and crudest of filters are effectual—a bag of limestone rubble and charcoal lumps at the intake will answer.

The treatment of water in bulk in a dam is not very satisfactory, as the main danger is in the mud at the sides; but any treatment that will precipitate floating matter is useful, such as lime, or bluestone, or sulphate of iron, all prescribed at the rate of 1 to 10,000, but quite safe at the more concentrated rate of 1 to 1,000, though at the latter generally rendering the water unpalatable. While if perchloride of iron comes down to reasonable prices again, about 3d. per lb., it is also useful and safe at the above proportions.

The same treatment may be adopted in the trough, but a weekly cleaning out is much cheaper and more effectual, though some scrap iron and a few lumps of lime at the inlet are useful and cheap. With regard to medical treatment, the time when it would have been of use is almost invariably past when it is commenced.

In veterinary hospitals excellent results are obtained by tapping the bowels and flooding them with medicaments which kill the worms therein; but such a proceeding is out of the question on the farm, where, if drenching has to be resorted to, a purgative such as a pint of raw linseed oil is useful, if combined with two tablespoons of painters' turps., in so much that some hundreds of adult worms are evacuated, but many thousands left behind; one or two teaspoons of chloroform added to the above increase the effectiveness of the mixture and the risk.

While to those that have unlimited time on their hands, and like giving balls to horses, the following prescription may appeal:—R ferri ammon. sulph., 2drs.; quin. sulph., 15grs.; acid carbol., 15m.; P. nux. vom., 20grs.; P. quassiae, 2drs.; P. digitalis, 10grs.; P. glycyrrh., 1dr.; theriac, q.s. M. ft. bol., 1. A ball to be given twice daily for a month. The writer is smiling up his sleeve while handing

out this, but it is a classic prescription. A useful worm powder is made of equal parts of sulphur, sulphate of iron, saltpetre, black antimony, linseed meal, and sugar; a dose is a flat tablespoon once or twice a day for some weeks in feed. This does not kill the worms, but facilitates their expulsion, and acts as a tonic. The writer fully admits the vermicidal properties of *santonine*, but at ten guineas a pound he fancies it is out of the question; if any should desire to use it, as much as will lie on a threepenny-bit is a fair dose for a horse, and can be added to the above powder if desired. The dose of tartar emetic is one dram, or a tablespoonful, and it can be substituted for the black antimony if desired.

But knowing the life history of the worms, and how the immature forms are in the blood vessels, and less resistant than the adults in the bowels, some drug which will reach them there is advisable; such a drug is arsenic, but it is a drug not to be played with, as at least one horse owner in South Australia has found to his cost, and the form recommended is Fowler's solution of arsenic, or liquor arsenicalis B.P., because B.P. means a standard dose at a safe margin. This is NOT A DRENCH, but two tablespoonfuls are mixed with the feed once a day for a fortnight, then the drug is discontinued for a fortnight, and repeated as before for a third fortnight.

Arsenic is very rapidly absorbed into the blood, and reaches the worms within a few seconds of its administration in the food, and in such a dose does not kill them nor the horse; but it prevents their sexual development, and at the same time acts as a tonic on the horse, so that its use may or may not be followed by the appearance of worms in the dung, but most certainly its action will be visible in the improved coat and condition of the horse.

The reason for stopping in the middle fortnight is that the liver has a special function of accumulating the drug, which during that fortnight continues its work, while otherwise there might be a small risk of its becoming too active if continued.

The few seconds only required for its administration render it a practicable means of dosing, and the solution being easily mixed with the feed ensures a safe and exact dose to each horse, which a similar amount of the crude drug does not; for if one horse got two doses he would very likely be upset. The cost works out at only twopence or threepence per dose at ordinary retail rates.

Finally, there is a bagful of truth in the hackneyed saying—  
Prevention is better than cure.

## GOVERNMENT INSPECTION OF STALLIONS.

## LIST OF CERTIFICATED HORSES.

*(Continued from page 730.)*

The list up to December 31st, 1914, of stallions certificated for life, is as follows :—

| Name of Horse.       | Age.    | Owner.                 | Address.         | Date.    |
|----------------------|---------|------------------------|------------------|----------|
| THOROUGHBREDS.       |         |                        |                  |          |
| Admiral Nelson ..... | 5 years | A. J. Berriman .....   | Saddleworth...   | 16/7/12  |
| Adrian .....         | 5 "     | M. P. McDonald .....   | Naracoorte ..    | 23/8/11  |
| Artillery .....      | 5 "     | W. T. Foster .....     | Quorn .....      | 31/5/12  |
| Banzai .....         | 8 "     | A. E. Press .....      | Hilton .....     | 6/3/12   |
| Ben Blair .....      | 5 "     | G. Ferne .....         | Wandearah...     | 1/8/13   |
| Ben Hur .....        | Aged    | Penny Bros. ....       | Saddleworth...   | 8/10/09  |
| Binnia .....         | "       | J. F. Kirby .....      | Mingbool.....    | 2/9/11   |

## ADVERTISING AUSTRALIAN PRODUCE.

"Matters are extremely unsettled as regards future shows in Great Britain, owing to the majority of halls having been commandeered for military purposes," writes the Trade Commissioner, under date London, March 19th. "There is," he says, "also an uncertainty as regards the holding of some of the leading agricultural shows, and I understand that it is quite possible that the West of England Show will not be held this season. Nottingham has been selected for the holding of the Royal Show this year. The Commonwealth are having their usual exhibit, embracing the whole of the States, but, apart from this, I do not think any individual States will be represented. The Victorian Government are now endeavoring to secure supplies either from London agents of Victorian manufacturers, or from manufacturers or producers themselves in Victoria, with a view of staging exhibits at trade shows and effecting sales to the trade generally. In fact, the tendency of most of the Australian States exhibiting at present is to endeavor to obtain some practical business results in return for the money spent on advertising, or, in other words, adopting the methods which South Australia instituted some years ago. I have noted the information regarding South Australian jam makers not being able to submit samples which I asked for some time ago, owing to the scarcity of fruit. I understand that the Contract Department of the War Office has now made arrangements for ample supplies for their future requirements, one order for 1,200,000lbs. being placed in Victoria."

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, April 14th. Mr. F. Coleman (Vice-Chairman) presided, and the following members were also present:—Messrs. A. M. Dawkins, C. J. Valentine, J. Miller, T. H. Williams (Chief Inspector of Stock), and W. J. Colebatch (Principal of Roseworthy College), Professor Perkins (Director of Agriculture), and H. J. Finnis (Acting Secretary).

### SHEEP VERMIN.

The committee appointed to consider the question of the vermin on sheep recommended that the present legislation be amended to give the Minister of Agriculture power—(1) To declare any portion or portions of the State affected areas, and (2) to draft regulations compelling owners of sheep within the affected areas to (a) dip their sheep, and (b) notify the Chief Inspector of Stock when such dipping had been carried out. The report was adopted, and the Board decided to send it as a recommendation to the Minister.

### COLONEL ROWELL.

Leave of absence for an indefinite term was granted to Lieutenant-Colonel J. Rowell, C.B., who is on service with the Expeditionary Force.

### CONFERENCES.

It was decided that conferences of Branches in the Pinnaroo and Brown's Well districts should be held at Tailem Bend in July. The Murray River Branches will hold their first conference at Renmark early in August.

### BELGIAN RELIEF FUND.

A letter from the Wilkawatt Branch was received suggesting that Bureau members be asked to contribute the product of three acres of next season's crop towards the above fund. It was resolved by the Board that the Branches be circularised to that effect.

### NEW BRANCHES.

Approval was given to the formation of new Branches at Warrow, Hilltown, Brinkley, and Wollowa, with the following gentlemen as members:—Warrow—S. A. Puckridge, H. Puckridge, H. J. Puckridge, R. Puckridge, R. J. Puckridge, J. J. Cuddleford, C. Cuddle-

tord, sen., C. Cuddleford, jun., J. C. Cowan, J. J. Foster, W. Doudle, H. C. Wilson, T. Lynch, J. Cuddleford, R. Hawson; Hilltown—S. Michael, J. D. Dall, J. A. Naismith, H. W. S. Frith, O. Dinham, F. Berthesmeier, H. Michael, R. E. Dinham, S. J. Scott, W. C. Jettner, J. B. Scott, C. Kostera, W. H. Jettner, J. Michael; Brinkley—W. Pearson, A. R. Martin, E. Schenschler, H. Pearson, H. Schultze, S. White, E. T. Humphrey, W. C. Humphrey, E. Pearson, W. Pope, P. Wilhelm, L. Usher, R. Adams, H. Humphrey, C. H. Forrest; Wollowa—J. T. Simper, A. K. Mallyon, C. K. Mallyon, V. O. Stone, W. E. C. Tuendemann, B. Tuendemann, O. H. Klose, G. R. McArthur, E. E. Magor, — Broadbent, C. E. H. Stone, A. W. Broad.

The following new members were also approved:—Yabmana—W. Dorey, S. Pengelley, G. Vorey; Gladstone—F. Pitman, J. Milne; Glencoe—William Smith; Riverton—N. G. Kelly, H. Sandercock; Millicent—J. T. William, W. J. Major; Salt Creek—B. H. Brannock; Coonalpyn—R. W. Kelcey; Maitland—B. Cornish; Booleroo Centre—Rev. D. C. Harris; Lameroo—C. Greig; Wirrega—F. W. Cook, E. A. Clark; Berri—C. Plush, J. E. Plush, L. Stearne, E. Foreman, J. Carpenter, W. N. Wilkinson, W. H. Bottrill, L. A. Chapple; Renmark—L. K. Eaton; Canowie Belt—G. M. Bray; Mypolonga—L. G. Cailles, G. H. Day, G. Kenaghan; Penong—W. Place; Strathalbyn—H. Goldfinch, jun.; Naracoorte—C. Malone; Lyndoch—H. Morgan; Wirrabara—W. G. Barbary; Borrika—W. M. May; Forest Range—N. W. Filsell; Yeelanna—P. Kain, A. Hubner, T. H. Proctor, A. E. A. Skipworth, C. J. Williams, J. J. Cronin, M. P. Cronin, J. P. Cronin, T. P. Neindorf, C. E. Kommermann; Elbow Hill—R. Ramsay; Mitchell—F. Farnham, J. Head, W. Voumard; Waikerie—V. S. Brown; Stockport—T. Hookings, J. Hookings; Geranium—F. Richards, J. Bowden; Woodleigh—P. R. Hodge; Ironbank—W. Warland, D. Leak; Two Wells—J. Rowe; Clare—J. Stanceliffe, H. Parey, A. Lehmann; Mount Remarkable—S. Challenger, Rev. S. R. B. Cornish, H. M. Mair, A. W. Cornish; Amyton, J. J. Naughton; Lameroo—Morsen, E. Henschke.

## PARAFIELD EGG-LAYING COMPETITION.

---

### FINAL REPORT.

By D. F. LAURIE, Poultry Expert and Lecturer.

---

*(Continued from page 744.)*

The subject of foods and feeding will for ever be of interest among breeders. Cost of production is an essential point. Locality and the nature of the grain crops and of commercial practice are potent factors. The food of one country or part of a country may be unobtainable or too costly in another country or portion of the same country. There are, however, many foods which, from their chemical composition, can be used but sparingly in some countries, and in none freely. Fowls are to some extent omnivorous; but in the case of fowls in confinement, and with a view to commercial success, care is needed in the selection and use of many foods. In all nine tests controlled by the writer, the foods used and methods of feeding have been as similar as it was possible to arrange. During the 1914-15 test more green food was used than in previous tests. The value of green food is better recognised than was formerly the case. The value of lucerne, both green and cured as hay, is worthy of the close attention of all breeders. Where used, the yolks of the eggs are always rich in color. From the list given in this report it will be noted that the variety of foods is not great, but it is sufficient. It would be of no practical use, and in my opinion quite wrong, to provide and use on an experimental station foods which cannot be and are never likely to be procured by the average poultry owner. Of the food used the principal grain is wheat, and the quality is always the best obtainable. Oats are occasionally used, but only when a particularly fine, bright, plump sample can be bought. Maize has its value for occasional use, and particularly, on account of its high fat content, for winter feeding. Maize is a bad grain to hold. Bran and pollard are the main constituents of the morning mash. Bran is valuable for its mechanical effect in making the mash crumbly, and for its mineral content (including phosphorus as phytic acid). In the pollard one gains good results from the minerals, and also from the high starch content which is converted into energy. Meat meal supplies the valuable animal proteins so essential to success in egg production. Lucerne hay chaff is freely used, and, as already stated, is a most valuable food. Grit is essential to success, and consists of sharp gravel, shell grit, and broken charcoal. The value of small charcoal for fowls from the newly-hatched chicken onwards, is but ill recognised by

breeders. Charcoal should be freely provided at all times and at all ages. Salt, used with discretion, is good for fowls, but not for ducks. Both the sodium and chlorine content are of value, in addition to making the food more palatable. Epsom salts (magnesium sulphate) and Glauber salts (sodium sulphate) are regarded as food adjuvants, not merely as medicines. In both the sulphur is split off, and has a better action than the crude mineral sulphur. As aperients and correctives they are each of great value, even when green food is abundant.

### HOW THE HEN UTILISES FOOD.

Few poultry breeders give much thought to what is involved in the processes of digestion, and in the utilisation of the components of food. Roughly speaking a hen requires food for the following reasons :—1. To keep up animal warmth and continuance of vital functions. 2. To repair waste tissue. 3. To store up flesh and fat in case of need. 4. To store a surplus for subsequent conversion into eggs. Fowls cannot masticate their food. It is first moistened with the saliva and stored in the crop, where it is acted upon by the diastase (ptyalin) contained in the saliva. Subsequently the food as it passes into various organs is mixed with numerous digestive fluids, each containing one or more ferments (enzymes), which cause chemical changes, generally a process of splitting into simple compounds ready for absorption by the various cells in the alimentary canal. The utilisation of food in the animal body is like the combustion of fuel in an engine. First comes the ingestion of the food and its subsequent storage in the different kinds of cells in the organism. Then comes the utilisation which is exhibited by the destruction of the cells which had multiplied as the effect of the food taken in. This destruction is actually combustion. Generally speaking the utilisation of stored food is spoken of as transformation of energy—the store being equivalent to so much energy. The value of foods is expressed in terms Calorie or calories (1/1000 of a Calorie). The values of protein and starch per grain weight differ considerably ; so also fat. The actual transformation of energy in domestic fowls has been studied at various times, and more recently by Gerhartz. This investigator carried out his experiments in a Regnault-Reserts apparatus, and adopted the customary unit of surface (1,000 square centimetres). Space does not permit of any detailed resumé of these interesting experiments, but the following results and conclusions are worth noting by modern poultry feeders. With birds in actual repose (both fed and unfed) he found the energy transformed in a fowl, and sufficient to keep up its physiological activity to be—Normal fasting fowl, 58·37 Calories ; normal fed fowl, 62·15 Calories ; broody hen, after feeding, 71·78 Calories.

Contrasting these results with those of other experiments (with dogs 75·10, and horses 94·8) he concludes that fowls in an absolute state of repose have

not a relatively high transformation of energy, but, a relatively low one. Experiments further showed that during moulting there was an increase in transformation of energy of 5.2 per cent. As regards the function of egg-laying, the results are still more interesting. During the period of egg production there was an increase of 70.1 Calories in transformation of energy, equal to 78 per cent. increase per unit of surface per day. Each day 43.9 Calories or 26.2 per unit of surface were employed in the formation of eggs. The experiments showed that admitting, without considering energy used in the formation and expulsion of the egg, the period of egg-laying increases energy transformation by 35 per cent., there would always remain 78 per cent. — 35 per cent. = 43 per cent. for formation and expulsion of the egg. The results are contrasted from another point of view—highly interesting but somewhat technical. The lesson one may learn from the experiment should increase knowledge on the subject of foods and their functions. Foods containing the necessary constituents and in a form admitting of quick and easy assimilation must be used where consecutive egg production is desired.

Over and above the needs for the vital functions a large amount of energy (food stored) is required, firstly for the formation of the egg, its elaboration, and again the physical actions taking place during the progress of the egg through the oviduct and its extrusion (laying); all this requires an expenditure of a large amount of energy. All this energy is transformed from the food originally ingested.

The routine followed in feeding the hens has been so often described that it is unnecessary to repeat. Those interested may, on application, obtain copies of former reports dealing with the question.

In the tables already given showing summary of results and foods and costs of food used, only Section 1 was included, so that comparisons with the results of other years might be made.

In Sections 3 and 4 individual birds only were concerned in the records. The figures given are what a private breeder would expect. The method adopted is to include all the food used in connection with the two sections. On April 1st, 1914, a certain number of birds (354) were penned. During the year a certain number died; others were disqualified because their eggs were under weight, and for this cause were assumed subsequent to July 31st to be of no value. Therefore only the eggs of those hens which laid eggs of standard size are included in the number and value of eggs laid. The cost of feeding represents the value of all the food used in the test, disqualified birds included. The combined result of Section 3 (White Leghorns) and Section 4 (general purpose breeds) is seen in the "profit over cost of food," 8s. 6d. per hen, which I consider an excellent record in a year of such high prices for foods.

## SUMMARY OF RESULTS.

|                                                |              |
|------------------------------------------------|--------------|
| Total number of birds                          | 222          |
| Total number of eggs laid, sections 3 and 4    | 38,552       |
| Total value of eggs laid, sections 3 and 4     | £162 2s. 2d. |
| Total cost of feeding                          | £67 13s. 6d. |
| Profit over cost of feeding                    | £94 8s. 8d.  |
| Average market price of eggs                   | 1s. 0-11d.   |
| Average number of eggs laid per hen, Section 3 | 194.9        |
| Average number of eggs laid per hen, Section 4 | 135.9        |
| Average cost of food per hen                   | 6s. 1-16d.   |
| Eggs laid by winning hen, Section 3            | 278          |
| Eggs laid by winning hen, Section 4            | 196          |
| Profit over cost of food per hen               | 8s. 6d.      |

## FOOD USED.

|                                                  | £    | s. | d. |
|--------------------------------------------------|------|----|----|
| Wheat, 199½bush. at from 3s. 6d. to 8s. bush.    | 47   | 2  | 4  |
| Bran, 135½bush. at from 1½d. to 2s. 5d. bush.    | 9    | 11 | 2  |
| Pollard, 418½bush. at from 1½d. to 2s. 5d. bush. | 32   | 3  | 5  |
| Meat meal, 12½cwt. at 18s. 6d. cwt.              | 11   | 4  | 4  |
| Lucerne chaff, 6½cwt. at 4s.                     | 1    | 6  | 3  |
| Grit, 19½cwt.                                    | 1    | 2  | 4  |
| Salt, 48lbs.                                     | 0    | 1  | 6  |
| Oats, 1½bush.                                    | 0    | 6  | 0  |
| Epsom Salts, 4lbs.                               | 0    | 0  | 6  |
|                                                  | £102 | 17 | 10 |

This includes food fed to disqualified birds, and also birds that have died.

## COMPARISON OF THE SERIES OF ELEVEN TESTS.

|                                        | No. of Hens. | Eggs Laid. | Average per Hen. | Eggs Laid by Winning Pen. |
|----------------------------------------|--------------|------------|------------------|---------------------------|
| 1st Test, held at Magill, 1903-4       | 156          | 20,630     | 132              | 1,032                     |
| 2nd Test, held at Roseworthy, 1904-5   | 186          | 21,701     | 117              | 1,251                     |

Section 1 only is included in these figures.

\* There were in each pen 10 pullets, as against six in the previous tests.

The eleventh test held in South Australia is probably the last likely to be held under these conditions. In this table Section 1 has the only records that can be used in comparison with former tests. There are only 340 hens in Section 1, whereas in the three sections last year there were 900. The final results show that notwithstanding the high price of poultry foods the 8s. 11·7d. profit per hen over cost of food points to the value of the hen as a national asset to any country.

Another point to be noted is that although thousands upon thousands of laying hens have been consumed on account of scarcity of grain, and that consequently the hens are not here now to provide the market with eggs, the average price is practically 1d. less per dozen than during the same period in 1912-13.

#### BROODINESS IN WHITE LEGHORNS.

In continuation of studies previously begun (*vide* report in 1913-14 competition), the further results obtained are interesting. In Section 3 all the pullets were single tested, i.e., each was separately accommodated in a small house and enclosed yard. Only 16 cases of broodiness were recorded among the 142 pullets figuring in the final records. The competition began on April 1st, and during that month, also May, June, July, and August, no cases were observed. In September there was one case, in October two, November four, December six, and January three. In February and March no cases occurred. The percentage of broody cases to the total number of pullets entered is only ·11.

In Section 1 there were 10 pullets in each pen, and no less than 102 cases among the 340 pullets in this Section were recorded. As was the case in Section 3, no cases were observed in April, May, June, July, and August. In September there were two cases, in October 21, November 31, December 34, January eight, February five, March one. The percentage of broodiness in this Section is therefore ·3, nearly three times as many as in section 3.

#### SEASONAL INFLUENCE.

From the above record, there appears to be ample evidence that seasonal influences are important factors. Practically the period from September until the end of March includes the normal breeding season, contingent on its duration upon other seasonal factors. I have already expressed the firm opinion that broodiness is a distinct character affecting breeding, and truly hereditary. Just as experiment has shown that certain characters appear only at certain stages of growth, so also does the reappearance of the masked character of broodiness coincide with the natural period. Whether or not broodiness is the immediate cause of enzyme action does not affect this conclusion. It may only be said that perhaps the condition favorable to enzyme action is linked with rising temperatures in spring and summer. Food, in particular as regards its components, has no doubt

an important role in the action of enzyme and co-enzyme, but at present I see no reason to credit, as some do, food with specific action in causing broodiness in White Leghorns. I look upon broodiness in White Leghorns as a reappearance of a lost character—strictly speaking a masked character. During the process of breeding, as carried out by many Leghorn breeders in Australia, the reappearance of the character of broodiness is an excellent example of what Professor Bateson (vice-presidential address British Association meeting, Sydney, 1914) terms a gradual unfolding. Holding these views, one cannot conclude otherwise than that broodiness in White Leghorns is due to segregation in the Mendelian sense.

#### TRANSMISSION OF BROODINESS.

There are at present many reasons why I am unable to conduct a series of experiments to demonstrate the mode of inheritance in broodiness. Doubtless scientifically it would be an interesting task. Practical commercial breeders will learn that broodiness is a characteristic to be eliminated in White Leghorns at all costs. Careful research in connection with thousands of White Leghorn hens and pullets reveals no ground for the assertion sometimes made that the hen which is temporarily broody recuperates, and is eventually the better layer. On the contrary, years of single testing show that the best layers never exhibit a desire to brood. From long continued experiment and observation I have formed the opinion that broodiness is transmitted equally through both male and female lines, and that non-broodiness is an ordinary recessive character. Constant watchfulness at all seasons is necessary if effective elimination is desired. Among the Government stud birds any hen showing the least suspicion of broodiness is discarded. Of course that does not end the matter, because there may be some of that hen's heterozygous progeny remaining, and in which the "broody" taint exists, although the recessives would be free. There is no doubt whatever that many breeders in the past have bred freely from stock in which the "broody" character was more or less common. Consequently it is going to take some time to regain lost ground.

#### TINTED EGGSHELLS.

Contemporary study was inaugurated in respect to the appearance of colored or tinted shelled eggs among the eggs collected from flocks of Leghorns. The normal egg of the White Leghorn should be pure white.

In Sections 1 and 3 accurate records were kept of all tinted shells. Curiously enough the number collected in Section 1 from 340 pullets was only 47, while from the 142 pullets single tested in Section 3 there were no less than 163. As previously pointed out, the pigmentation of eggshells is due to products, originally of hepatic origin, secreted by certain glands in the oviduct. It would seem that this factor—the tinting of eggshells—is affected by some

seasonal influence. It is common knowledge that in this State hens which lay tinted (even deeply) eggs lay those of richest color in autumn and winter, and that in the warm weather the tinting is very much less marked. All through the year the birds had abundance of green food daily, so that the mineral salts in green fodders cannot affect the question. As reported in reference to the 1913-14 test, the production of tinted eggs is restricted practically to autumn and winter, and a few in spring.

In Section 3 there were 42 tinted eggs in April, 100 in May, 18 in June, two in July, and one in August. From then until the end of the test on March 31st no tinted eggs were observed. In Section 1 the tinted eggs recorded were four in April, 16 in May, 14 in June, four each in July and August, three in September, and one each in October and November, and nine for the remainder of the year.

It is noteworthy that in the Government stock at Parafield the tendency to lay tinted eggs has apparently been checked: no tinted eggs are seen.

#### THE BREEDING OF LAYERS.

Many years ago when I pointed to the bad practice of many breeders who selected pullets as stock birds, there was objection. Nowadays the wisdom of breeding from hens not younger than two seasons is almost universally recognised. Immature stock will not breed sound, vigorous progeny. In my earliest publications stress was laid upon the breeding of the male bird equally with that of the hen. It was pointed out time after time that unless the male bird in the breeding pen were the son of a hen distinguished by high laying, the pullets would be as a rule poor layers, despite the fact that the hens bred from had done well. Then again the fact was accentuated that improvement in size of eggs could only be effected through the male side, *i.e.*, by using as a sire a bird bred from a noted layer, the eggs from which were large. These two points have been corroborated in America, although they had attained practical importance here some years previously.

In selecting stock for breeding purposes it will be found that the task is continuous year after year. It may be taken as a fundamental axiom as related to breeding that you cannot stand still; you must progress or recede. Even with stock in which the characters of large eggs and good laying are fixed, there are other important factors. Size, type, and constitution are important points, and need constant attention. I have already referred to undesirable features in White Leghorns, such as broodiness, tinted eggs, &c. Want of balance in breeding tends to production of vicious stock—chronic feather and egg eating—cannibalism. Then again there is the hereditary tendency to disease and lack of resistance. All these points may well occupy the mind of those who intend to make commercial breeding the success it should be. It is to your foundation stock and the methods you adopt that you must look for continued success as a breeder.

### WHEN SHOULD COMPETITIONS BEGIN ?

This is not a new question. Some years ago I referred to the matter and expressed the opinion that in South Australia the tests should start on March 1st instead of April 1st. Despite the fact that there were many objectors, there is sufficient proof that March 1st is the time ; moreover, most practical breeders agree to that date. I am referring to this question, not because there may be other tests in years to come, but in consequence of the many facts which show that White Leghorns, which are only just about to lay on April 1st, are hatched too late, and are not as fine specimens, on the average, as those hatched, say, a month earlier. When April 1st was first decided upon as the proper date, the experience which showed when pullets would lay was all gained from exhibition stock, not bred for egg production. Again, April is often a month of changeable weather—now cold, now hot. These changes often bring about heavy moulting. The fact that for years the pullets in the laying competitions, with few exceptions, have started to moult within a few weeks of April 1st, is against the assertions of breeders generally. For market, egg-production pullets which are not laying before April 1st are generally poorly developed, and show frequent tendency to moult. Late hatched pullets do not pay.

### EGG-PRODUCTION TABLES.

The appended tables show—(1) The monthly scores of each pen of 10 pullets in Section 1. (2) The individual scores of all the pullets in the single testing sections (3 and 4) which were not disqualified or which had died. The weight of eggs laid by each pen in Section 1, and of each pullet in Sections 3 and 4 is also given.

### RESULTS OBTAINED.

During the progress of the tests held at the Government Poultry Stations, a mass of valuable data has been accumulated. It is hoped that at no distant date it will be possible to dissect these figures and deal with various points elucidated during the whole period.

D. F. LAURIE, Poultry Expert.

## THE AGRICULTURAL BUREAU.

---

### CONFERENCE OF THE SOUTH-EASTERN BRANCHES.

The Annual Conference of the South-Eastern Branches of the Agricultural Bureau was held at Mount Gambier on Wednesday, March 24th. Among those present were the Minister of Agriculture (Hon. T. Pascoe, M.L.C.), the Director of Agriculture (Professor Perkins), the Wool Instructor (Mr. Henshaw Jackson), the Dairy Expert (Mr. P. H. Suter), the inspector of the Government experimental plots in the South-East (Mr. E. S. Alcock), Messrs. F. Coleman (vice-chairman), G. Jeffrey, and C. E. Birks (members of the Advisory Board of Agriculture), H. J. Finnis (acting secretary of the Board), and numerous delegates representing the Branches in the South-East.

The Conference was presided over by the chairman of the Mount Gambier Branch (Mr. R. P. Pritchard), who extended a hearty welcome to the visitors.

The Minister, in declaring the conference open, said the visitors from Adelaide had admired the beautiful gardens in the heart of the town, which presented a marked contrast to the burnt-up plots in Adelaide's suburbs. The exhibits in the hall showed a quality that spoke volumes for the productiveness of the soil. In his opinion, they were only just finding out what the district could do. Some of them had been doing well in the past, but there was not the slightest doubt that the South-East would do a great deal more for the State in the future. One of the things that would effect improvement was the growth of the Agricultural Bureau system. Instead of letting a man paddle his own canoe, it provided means for the profitable interchange of opinions, and the elucidation of local problems. He believed the Bureau system would have a wonderful influence in increasing production. In the South-East alone there were 16 Branches, with an aggregate membership of 381. He alluded to the changes in the department that had resulted in the promotion of Mr. W. J. Colebatch, who had inaugurated many promising experiments at Kybybolite. These would still be carried on by the department with advantage to the whole of the State. He reminded them that the Director expected them to take more interest in the work, and that when asked by farmers to establish experimental plots, he required a Branch of the Bureau to be formed in the dis-

tract. The value of plots was lessened considerably unless the district farmers took an active interest in them. He knew of instances in other districts where the plots had not been visited by more than one or two farmers. There were seven places in the South-East where tests were being carried out, and it was "up to" the man on the land in the vicinity of each to watch the various stages for the purposes of comparison. Unfortunately, the bad season had caused the Director of Agriculture much additional work, as he was the Chairman of the Grain and Fodder Board. They had purchased 740,000bush. of wheat for seed purposes, 20,000bush. of oats, and had imported 35,800 tons of fodder. Grain had also been purchased for feeding purposes. If outside purchases of fodder had not been made, all the supplies in the State would have been eaten up by the middle of July. The Government had done their duty, and had expended over one million pounds to help the producer, and the result was that it had been made possible for farmers to crop one million acres more during the coming season than would otherwise have been possible. He was certain that, given a good season, most of the money lent to the farmers would be repaid next year. He had much pleasure in declaring the conference open, and he hoped the coming season would be a prosperous one for the producers of the district.

Professor Arthur J. Perkins delivered an address on "Forage Crops," which is reported fully elsewhere.

The afternoon session was opened by the Wool Expert (Mr. Henshaw Jackson), who devoted his remarks to advice regarding sheep suitable for the farmers of the district. He advocated that the farmers should gradually go in for a uniform type, both as regarded wool and carcass, and lambs. In this way they would hold out a bigger inducement to buyers, and this would mean a higher price. In regard to the breed suitable for the farmers of the district, he favored a cross between a Leicester and a Lincoln ewe to get the ewes from which to breed their lambs. To these mothers he would put Southdown rams for breeding lambs. The reason for his choice was that he believed in quality. He was not speaking of the present, and it would take time to breed up the ewes, but if the farmers agreed among themselves they would find that men would go in for breeding the ewes for them, and they could buy these for lambraising. Following on the address given by Professor Perkins, he would strongly advocate the hand-feeding of sheep. People seemed to think that the sheep was the only animal they should not hand-feed, and yet he had proved that they could be made as domesticated as the dairy cow, and very profitable at that. When

sheep sold for a few shillings a head, hand-feeding was out of the question, but now that they brought more than a pound, the time had come for closer attention to be paid to the matter of feeding. It would pay them to market their fodder in the hides of sheep instead of in bags. Several questions were asked afterwards, and a number of sheep-breeders contended that the Lincoln-Merino cross, persisted in, was better than that advocated by Mr. Jackson. To this he replied that their cross was a good one, but he preferred his for quality, and he thought that would make up for any deficiency in weight of either carcass or wool.

The following paper on "Testing Dairy Cows" was read by Mr. P. H. Suter (Dairy Expert):—

Whilst much good has resulted from the testing of farmers' cows in other lands, little has been done upon systematic lines in this State. Many factors, such as judicious feeding, breeding &c., contribute to the profits made in dairy practice; one perhaps least noted, however, by those so engaged, and yet very important, is the ability of the dairy cow to yield milk and butter economically. Numerous investigations made amongst the herds of Australasia and other countries have conclusively proved that many members of the dairy herds are returning value in dairy products much less than the cost of their keep, covering only food and labor.

What is true of other dairying centres in this respect is only too true of the dairy herds of South Australia. In this State we have approximately 100,000 cows, included in that number being scores of thousands which (had true records been made) would, on computing the production covering the period of lactation, have shown that they were being kept at a loss, after deducting the cost. The effect of this condition upon the profits made, though hard to estimate, must total a very huge amount if reduced to £. s. d., possibly not less than £250,000 per annum.

Admitting that the percentage of cows kept at a loss varies very considerably in our herds, it would, I feel, be difficult to find 2 per cent. which have not some members not paying their way. These duffers or non-profitable milkers are responsible for failures, and in other instances of only moderately successful returns being made by their owners. The testing of our dairy herds, whether carried out individually by the farmers or under some form of co-operation, has for its object the betterment of the dairy type and returns. Success depends upon improved management, embracing intelligent feeding and breeding. Within the herds of our State are to be found some most excellent and efficient milk-makers; but owing to carelessness

and indifference to feeding and proper management, these are proving little if any better as profit-makers than are those less efficient in that respect.

Recognising most fully the great need that exists for improvement in the breeding and selection of our dairy stock, I feel that before extending the practice of testing with the Babcock tester and scales, farmers should see to it that they first insure to their cows a sufficiency of suitable fodder. This being provided (be it silage, green fodder, hay, concentrates, &c.), they are then able to place each cow on a fair trial as to her merit as a milk and butter maker. I am well aware that in some localities difficulties obtain in providing that a suitable ration shall be fed through the whole period of lactation; but I am equally sure that better provision than at present exists can be made in this respect at almost every farm in the State.

There are some districts wherein those engaged in dairy practice could (by testing, weighing, culling, and giving greater attention to the feeding) readily double their present returns per cow per annum. It is especially in these districts that most careful and immediate attention should be given to the formation of testing associations, more particularly as farmers are dependent upon the dairy cows to largely augment the returns from the farm.

With a view to supplying some reliable local data to our dairying folk, the Department of Agriculture is now engaged in testing and recording the milk and butter yields of the individual cows within the herds of our prominent stud breeders. Authenticated fortnightly tests are taken under the supervision of a departmental officer, and are continued with each individual cow throughout the full period of lactation, from year to year. Stud breeders are finding that even in their carefully bred herds certain members are not paying for their keep, and whilst it is hard to discard them, they are not hesitating to do so, realising that such must be done if profits are to be made.

Records kept of stud stock throughout the full period of lactation, and officially controlled, are not alone a valuable guide to stud owners, but are of great value to the dairyman who is desirous of getting improved returns through the services of pure-bred sires possessing undeniable milk-blood within their veins. Such records at the same time clearly supply to breeders and intending buyers alike an almost correct estimate of the quantity and quality of milk and butter produced, together with the staying capacity of each cow.

Where testing records are now being kept a charge is being made of half a guinea per head for each stud cow placed under test by breeders. At the conclusion of the period of lactation a Government certificate of production is issued.

Below will be found the regulations for the Government certificate of standard cows confined solely to pedigreed herds. The main object of these certificates is to supply reliable data to purchasers of stud stock, and thus to assist breeders to improve the producing capacity of their herds. Pedigree and show-yard performances have been the main consideration of the past, milk and butter production not receiving first consideration, as must follow under the present system of keeping records.

Stud Jersey Cows, Property of Mr. H. C. Toppin, Plympton.

More weight should in future be given to performances at the bucket when awarding pride of place or prizes at our shows. Good dairy performance, form, and purity of blood must take preference to pedigree and form alone, and buyers, when looking for good stock, will willingly pay higher figures when making their purchases.

#### REGULATIONS CONCERNING HERD-TESTING FOR THE GOVERNMENT CERTIFICATION OF STANDARD COWS.

1. The owner of any herd of pure-bred dairy cattle may submit his herd for certification.
2. An annual fee of 10s. 6d. per cow shall be paid to the Department of Agriculture on demand.

3. All cows not possessing a brand will be marked on the inside of an ear with the Government tattoo and identification marks.

4. Testing and recording shall occupy a period of nine calendar months, commencing one week from date of calving, excepting under such circumstances as set forth in clause 17. This period shall be recognised as the official lactation period.

5. The milk from each cow shall be weighed at least two days in each month, in the presence of the officer, and a sample taken for testing purposes—morning and afternoon.

6. Additional visits may be paid by the supervisor, but the average weight and test of two days monthly shall constitute the daily yield for the month.

7. Particulars as to date of calving, service, drying off, hours of milking, and manner of feeding must be supplied for record purposes, on the request of the dairy supervisor.

8. If deemed necessary, the owner may be called upon to furnish a statutory declaration as to the correctness of such or any particulars.

9. Tests will be carried out by the supervisor, and samples shall comprise amounts in proportion to the yield. The results, unless shown to be abnormal, shall be considered as the average for the period intervening since the next previous normal test. If apparently abnormal, the results may be discarded, and further samples taken and tests made.

10. Standard cows under these regulations shall be those which, during the official lactation period, yield—

(a) 150lbs. of butter on first calf.

(b) 200lbs. of butter on second calf.

(c) 275lbs. of butter from cows commencing any lactation period other than first or second.

11. A Government certificate shall be issued in respect to all standard cows. Such certificate shall show the breed, the age at entry, brands, the official lactation period recorded, and the date of completion, the weight of milk given, the amount of butter-fat and commercial butter (estimated on a 15 per cent. over-run), and the weight of milk given on the last day of the official lactation period.

12. The certificate issued in respect to any standard cow shall, if she attains the standard during any subsequent lactation period, be returned to the Department, when a fresh certificate will be issued, which will show her record for each and every lactation period in which she was tested.

13. Cows eight years old or over, whose yields have been recorded for three official lactation periods, may be exempt.

14. Aged or injured cows in the herd at time of entry, and kept for breeding purposes, may be exempt on the recommendation of the supervisor. Any injury interfering with the lactation period subsequent to entry may be recorded on certificate issued.

15. Any cow which on veterinary examination is found to be affected with tuberculosis shall be withdrawn from the test, and her milk shall not be allowed to be used for sale or for the preparation of any dairy produce for sale.

16. Any cow which on veterinary examination is found to be affected in the udder, or by any other disease or condition which may temporarily render her milk injurious, may remain in the herd for testing, but her milk shall not be used for sale or the preparation of any dairy produce, without permission of the supervisor.

17. When any newly-calved cow is rendered temporarily unfit for testing by being affected with milk fever, mammitis, retention of the placenta, or any other ailment affecting newly-calved cows, the period elapsing between calving and entrance to the official lactation period may be extended, on the recommendation of a veterinary officer or supervisor, but such period shall not exceed one month from the date of calving.

18. Any interpretation or decision in respect to these regulations, or in respect to any other matter concerning the certification, which receives the written approval of the Dairy Expert, shall be final.

19. Should the owner of any herd entered not conform to these regulations, such herd shall be subject to disqualification for such period as the Director shall determine. The Director retains the right to withdraw any certificate when to his satisfaction good and sufficient cause is shown.

20. Owners will be supplied with a monthly statement setting out the amount of milk, butter fat, and commercial butter yielded by each cow.

21. Each monthly report is supplied solely for the information of the milk producer, and must not be used as evidence in case of any dispute between seller and buyer, or where the quality has been questioned by any public authority.

22. For the period mentioned in clause No. 17, of cows being sick, such cows shall be credited with the average yield and test calculated by taking the previous and following month's record; or in the event of cows just calved, the average for the two following months shall constitute her yield for that month.

23. The supervisor can call upon the owners of herds any two days he may choose in each month.

"Rose" is the property of Mr. H. C. Topping, of "Kiama Farm," Plympton, South Australia. Whilst not a cow of large frame, she shows nice quality, and has proved a most consistent milker. On the last day of her nine-months' test she was readily yielding 18lbs. of milk per day, in face of the fact that her owner was trying to dry her off. It will be noted in the certificate below that her record shows for nine months only, whereas she continued milking right up to calving, giving 16½lbs. of milk the day prior to this taking place. She yielded in all 511lbs. extra milk over her nine

"Rose of Kiama," Jersey Farm, Plympton.

months' record, producing 26lbs. extra butter, thus making her actual record 6,098lbs. of milk, producing 371.4lbs. of commercial butter, entitling her to a first-class certificate of production.

Notwithstanding "Rose's" excellent performance, she did not get the very best conditions under which to show her fullest capabilities as a true dairy cow, her condition being low when calving, and no spring pasture obtained during the season she was under test. "Rose" was also mated too early with the bull, which affected the milk yield during her trial, and shortened the period of lactation. Valuation of the milk and butter produced by "Rose" at 1s. per gallon for retail purposes, and 1s. per lb for butter, shows a return of £30 10s. and £18 11s. 6d. respectively.

[CERTIFICATE OF PRODUCTION.]

This certifies that the Jersey cow "Rose," branded **b** near ear, and owned by Mr H. C. Toppin, Adelaide, South Australia, produced the following amounts of milk, butter fat, and commercial butter during the period January 1st, 1914, to September 30th, viz., 5,587lbs. of milk with 300.5 lbs. of butter fat with 5.42 average per cent. of fat. The records have been made under the supervision of this Department in accordance with the rules governing official test of cows.

"Cremorne."—One of the Jersey Sires used at the Farm of Mr. H. C. Toppin.

### THE 1916 CONFERENCE.

At the afternoon session it was decided to hold the next Conference at Kalangadoo.

### EXHIBITS.

A fine display of exhibits was staged in the hall. Among those which claimed attention were pumpkins grown by Mr. G. Warner, of Penola; Eclipse maize, grown on unirrigated land by Mr. S. Ockley, of Penola; maize and sorghum 5ft. to 7ft. high, staged by Mr. W. Simpson, of Mil Lel; and Ninety-day maize, produced by Mr. A. H. Sassanowsky. Samples were shown by Messrs. Buchanan Bros. of Duckbill barley taken from land which produced 43bush. to the acre after being cropped for 11 years in succession. A comparison between the cereal growth in 1913 and last year was strikingly illustrated by sheaves of oats grown by Messrs. R. Smith and A. H. Sassanowsky respectively. Mr. G. Holloway, of Merna Estate, exhibited kale sown broadcast at the rate of 4lbs. of seed to the acre on October 1st, 1913, and helped with a small quantity of mineral super. broadcasted over the land before harrowing. The plants were vigorous and healthy, although they had once been fed down by stock. Rape sown on similar soil was spoiled in March by aphids. Messrs. McArthur Bros., of Rendelsham, exhibited a bag of potatoes taken from a heavy crop grown on land adjacent to the Mount Hope drain.

The delegates and visitors were entertained to luncheon by the Mount Gambier Branch, and the usual toasts were honored.

Haymaking

## THE WHEAT MARKET.

| Date. |    | LONDON (Previous Day).                                                    |
|-------|----|---------------------------------------------------------------------------|
| April | 6  | Steady; slightly firmer.                                                  |
|       | 7  | Steady, quiet.                                                            |
|       | 8  | Dull, offered lower.                                                      |
|       | 9  | —                                                                         |
|       | 12 | Steady, quiet.                                                            |
|       | 13 | Firm, held higher; Liverpool firmly held at full rates but inactive.      |
|       | 14 | Steady, quiet.                                                            |
|       | 15 | Firm, held higher.                                                        |
|       | 16 | Firm, held for 3d. advance; Liverpool firmly held but inactive.           |
|       | 19 | Firm, rather dearer.                                                      |
|       | 20 | Firm, held for 6d. advance.                                               |
|       | 21 | Dull, easier tendency; Liverpool firm but quiet.                          |
|       | 22 | Firm, quiet.                                                              |
|       | 26 | Very firm, 6d. to 1s. advance asked; Liverpool firm at 3d. to 6d. dearer. |
|       | 27 | Quiet.                                                                    |
|       | 28 | Dull, offered lower.                                                      |
|       | 29 | Unchanged; Liverpool firm.                                                |
|       | 30 | Steady; no quotation.                                                     |
| May   | 3  | Quiet.                                                                    |
|       | 4  | Firm, but quiet.                                                          |
|       | 5  | Firm, rather dearer.                                                      |

The price of wheat in South Australia was quoted at 7s. 3d. per bushel for ordinary f.a.q. on trucks Ports Adelaide, Pirie, and Wallaroo at the beginning of the month. There was an advance of 3d. on April 22nd, since when the market has remained steady at 7s. 6d. per bushel for growers' lots.

The value of milling parcels on May 4th ranged from 8s. 3d. to 8s. 4d. on trucks at Port Adelaide. In Victoria on May 3rd the price of wheat was nominally 8s. to 8s. 1½d. per bushel. The prices officially fixed in New South Wales and Western Australia, viz., 5s. and 7s. 4d. per bushel respectively, remained unchanged.

## DAIRY AND FARM PRODUCE MARKETS.

A. W. Sandford & Co., Limited, report on May 1st—

**BUTTER.**—The effects of the very dry weather experienced previous to the good rains that were recorded early in April, combined with the fact that the State of New South Wales has prohibited the export of butter, has so shortened supplies that prices have substantially advanced, and "Alfa" is now selling at 1s. 11d. per lb.; "Primus," 1s. 10½d.; choice separators and dairies, 1s. 8d. to 1s. 9d.; well-conditioned store and collectors', 1s. 5d. to 1s. 6d. per lb.

**EGGS.**—Demand not being quite so keen, values have eased a little, good turnover being recorded. Present quotations—Hen eggs, 1s. 7d. per dozen; duck, 1s. 8d.

**CHEESE.**—There was an advance of 2d. per lb. during the month, owing to the decrease in local supplies, and some parcels from the Eastern States are finding their way to this market. Quotations, 11d. to 11½d. per lb. for large to loaf.

**BACON.**—High prices have ruled throughout April, and these have attracted interstate consignments, which have had the effect of reducing the market somewhat. Best factory cured sides are selling at 10½d. to 11½d. per lb.; hams, 11d. to 1s. per lb.

**HONEY.**—Record figures have been realised in this line, quantities coming forward not being nearly equal to demand. Prime clear extracted, 5d. per lb.; beeswax, 1s. 3d. per lb.

**ALMONDS.**—Purchasers have been unable to fulfil orders, kernels especially being exceptionally scarce, and the season is now practically over. Present quotations—Brandis, 8½d.; mixed softshells, 7½d.; hardshells, 4d.; kernels, 1s. 7d. per lb.

**LIVE POULTRY.**—Heavy catalogues have prevailed through the month, with advancing prices, and supplies becoming scarce, so that good rates are likely to rule for some time to come. Heavy weight table roosters fetched 3s. 6d. to 4s. each; nice conditioned cockerels, 2s. 9d. to 3s. 3d.; plump hens, 1s. 9d. to 2s. 6d.; fair conditioned hens and light cockerels, 1s. 3d. to 1s. 6d.; ducks, 2s. to 3s.; geese, 3s. to 3s. 9d.; pigeons, 4d. to 5d.; turkeys, from 7d. to 11d. per lb. live weight for fair to prime table birds; fattening sorts, lower.

**POTATOES AND ONIONS.**—The position of the potato market has altered very little since our last report. The Millicent district still continues to contribute limited supplies, but the greater portion of our requirements are being imported from Victoria. Onions are plentiful, and prices weakened slightly. Quotations—Potatoes, £6 to £6 10s. per ton of 2,240lbs. on trucks Mile End or Port Adelaide; onions, £6 to £6 10s. per ton of 2,240lbs. on trucks Mile End or Port Adelaide.

### THE MARGARINE MENACE.

Reporting to the Minister of Agriculture under date London, March 19th, the Trade Commissioner writes:—"Compared with last year's shipments, Australian butter arrivals to date show an appalling shortage. Extraordinary values are being realised for all grades, with every possibility of further increase in prices. In consequence of the extremely high prices which retailers are forced to charge for butter, the demand for margarine has increased enormously. Manufacturers of this product are experiencing the greatest difficulty in obtaining supplies of edible fats, which are so largely employed in the manufacture of margarine. Whilst it is, no doubt, a source of gratification to the butter shippers in Australia and New Zealand, who are participating in the high prices ruling at present, there is, however, one feature which cannot fail to be taken into serious consideration, and that is the enormous increase in margarine consumption. Undoubtedly, margarine has become firmly established on these markets as a strong competitor of the lower grades of Australian butter, but to-day its consumers have increased so largely that we can look forward to more vigorous competition in the future. I am not at all surprised at this, as I have sampled several of the higher grade margarines on sale here, and find them cleanly made, wholesome, and, from a flavor standpoint, infinitely superior to secondary butters of doubtful storage age and Australian origin which are occasionally met with in Tooley Street. Retail prices to-day are as follows:—Butter, 1s. 6d. per lb.; margarine, 6d. per lb.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of April, 1915, also the average precipitation to the end of April, and the average annual rainfall.

| Station.                   | For April, 1915. | To end April, 1915. | Av'ge. to end April. | Av'ge. Annual Rainfall | Station.               | For April, 1915. | To end April, 1915. | Av'ge. to end April. | Av'ge. Annual Rainfall |

\* No report received during the month of April.

† Formal report only received.

‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

### May 12th, and June 9th, 1915.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

Edited by H. J. FINNIS.

#### UPPER-NORTH DISTRICT.

(PETERSBURG AND NORTHWARD.)

AMYTON (Average annual rainfall, 11.82in.).

March 29th.—Present: seven members and one visitor.

DOES FARMING PAY?—Mr. T. Ward, in a short paper, initiated a discussion on this subject. He contended that farming was not profitable if wheatgrowing was depended upon solely. It was only profitable when each branch of farming was worked in conjunction, and each made to help the other.

PREVENTION OF DRIFT.—Mr. J. J. Naughton read a paper on this subject. In the discussion that followed members considered that the plough was the best thing to remedy the trouble.

MORCHARD (Average annual rainfall, 11in. to 12in.).

March 27th.—Present: 14 members.

CLEANING FALLOW LAND.—Mr. W. A. Toop read a paper on this subject, in which he advised all farmers with a holding of 1,000 acres to work under the three-years system. The fallow could then be cleaned of weeds by sheep, which was far more economical than using the cultivator. In addition, the sheep would enrich the soil with their droppings. Should the crop come up dirty, it was best to mow it for hay, as that had the effect of cleaning the land. It should be cut on the green side, so that the seeds would not drop out. The paper was well discussed. The hon. secretary then read a paper on "Blacksmithing," written by "Agricola," which was well discussed by members.

WIRRAWARA (Average annual rainfall, 18.91in.).

January 30th.—Present: 21 members.

USE FOR WORN-OUT IMPLEMENTS.—Mr. J. Hollit contributed the following paper:—"The old double plough, which has long since gone out of date in these parts as a plough, could be taken to pieces, and the two long beams and handles straightened. Some of them having the eye already formed could be used for the top and bottom of the frame of a gate, and act as the hinges, while the two end pieces could be made of wood or iron, whichever was the most convenient for the person making the gate. After the frame was made and well stayed it could be enclosed with pig netting or hoop iron. This makes a very serviceable gate, especially for division fences. If the seed drill is taken to pieces, almost every part will be found useful. The two wheels put on a short axle, say about 3ft. in the clear between the wheels, and one of the poles makes a splendid post lifter. Place the big end of the pole about 9in. or a foot over the axle, get a stout piece of iron, split and make a claw one end, place it on top of the pole with the claw hook just projecting far enough to allow the chain to work easily. A good plan is to have a chain with a ring in one end to fasten round the post, and the claw hook will grip the link where required. This is a very easy way to pull down old fences. The post lifter made as suggested is very handy for moving heavy weights. I

have taken big strainers along a line of fence with mine by swinging the strainer between the wheels and fastening the small end to the pole and then tying the pole to the axle of the buggy when the draught horses have been in work. The seed and manure box make a useful feeder by taking out the seed and fertilizer feeders and the partitions. The boards taken off the box are more than sufficient to put in the bottom and complete the feeder. A good gate can easily be made out of the frame of the drill, in fact the frame is already made, all that is required is to take the piece of iron off the middle, and place it on the back, which will form the top of the gate, and put the hinges on. The gate can be covered with strong pig netting, hoop or light flat iron. This will make a strong gate for a piggery or any gate where a large opening is not required. The axle can be used for a shafting for any light work, and there are still some good bolts left which, if taken care of, will come in handy on the farm. The Hawke seedsower can be turned into a machine for turning an emery stone, &c., in fact, it is already made. All that is required is to take off what is not needed, place the handle on the spindle where the wheel belt has been taken off, put the emery stone on the spindle, from which the fans have been taken, and then you have one of the handiest machines you have on the farm. Many parts of the reaping machine can be put to good use. The drum is a good trough for feeding calves, &c., and the back door will answer very well for a door of a calves' pen which is already made. The box is a good house for dogs, fowls, or even pigs, if placed in the piggery for the pigs to go in and out as they choose, while the wheel, axle, and platform can easily be turned into a good water cart by pulling the platform and steering wheel into the centre, and with a few pieces of timber forming the bottom or frame work for tank. The cart is then complete, with the exception of pole or shaft; either can easily be put on. A water cart of this description is very handy on a farm to take water into the hay yard for damping the hay before it is chaffed or any other purposes where water is required. The beaters placed on end make a good flower stand, or by laying them down flat on a piece of wood makes a splendid place for killing and skinning sheep, thus keeping the skin clean."

#### WIRABARA (Average annual rainfall, 18.91in.).

March 27th.—Present: 23 members and visitors.

LUCERNE GROWING.—Mr. E. Pitman read a paper on this subject. Most of the failures experienced by lucerne growers, he said, were due to either faulty preparation of the ground or poor seed. Lucerne, if properly treated, would last from 15 to 20 years. The ground should be fallowed as deeply as the soil would permit, and kept well cultivated through the summer months, to ensure the destruction of all weeds and to conserve moisture. He favored sowing local-grown seed, as it obviated the danger of introducing dodder and other weeds, and ensured the freshness of the seed. Seed should be sown in April or May, 9lbs. to 10lbs. per acre if drilled, and more if broadcasted, with 2wt. of super. Stable manure should not be used until the plant had obtained a good start, and after that, it should be put on and worked into the ground well every spring and autumn. If lucerne were to be fed off, it was advisable to put on all the stock at once, in order to feed it off in the shortest possible time, as it would then quickly recover. Without irrigation the grower could not expect to get more than two or three cuts in the year, but with a good supply of water and manure lucerne should be fit to cut every three or four weeks. The best time to cut was when the crop was about one-third in flower, as it would then grow again more quickly than if left until later. Dealing with the various varieties of lucerne he said that Hunter River and S.A. seed were both good, but Arabian lucerne had not proved a success.

ORROROO, January 23rd.—CARE OF HARNESS.—Mr. J. B. McDougall read a paper on this subject, and said that on purchasing new harness it was advisable to at once give it two or three coats of neatsfoot oil, to fill up all the pores, and so keep out rain and sweat. Harness should be thoroughly overhauled after each seeding, fallowing, and harvest. If dirty, soft soap and warm water should be used, and when nearly dry the leather should be coated with oil. Repairs should be promptly attended to, and not patched up with wire. Harness should never be soaked in boiling water, as it spoils it and rendered it brittle.

QUORN, March 27th.—Mr. C. Patten read a paper from the *Journal* on "The Drought." In the discussion which followed members advised sowing three-quarters of a bushel of wheat to the acre this year.

WEPOWIE, March 30th.—In reply to a question, Mr. Roocke said that horses would readily eat sorghum when it was in seed. A further question elicited the reply from Mr. Orrock that owing to the dryness of last winter and the total failure of the crop, the super. used then should retain about half its original strength.

WILMINGTON, March 3rd.—A paper on "Co-operation," written by Mr. Nairne for the Annual Conference was read by the Secretary. A discussion followed.

### MIDDLE-NORTH DISTRICT. (PETERSBURG TO FARRELL'S FLAT.)

BEETALOO VALLEY (Average annual rainfall, 18in. to 19in.).

March 28th.—Present: six members.

THE PREPARATION OF LAND FOR SEEDING.—Mr. Flavel read a short paper on this subject. He said that in preparing land for seed it should be first ploughed to a depth of about 4in. not later than August, then harrowed with a heavy harrow, and finally cultivated to a depth of about 2½in. The middle of April was the best time to sow, but in dry years it was not advisable to commence before May. If the land was dry it should be rolled before the drill, to give the seed a firm bed. He favored Marshall's No. 3 and Marshall's Hybrid for hay wheats, and King's Early, Gluyas, and Federation for early wheats. A good discussion followed the reading of this paper, one member advocating the use of sheep in preference to the cultivator.

CANOWIE BELT (Average annual rainfall, 20.04in.).

March 4th.—Present: 11 members.

BARE FALLOW OR THREE YEARS SYSTEM.—Mr. Daly said that in this district the three-years system on holdings of from 400 acres to 500 acres could not be worked successfully. By bare fallow over 200 acres of well-worked land could be under crop each year, and by cutting straw and mixing it with hay chaff a good number of stock could be carried. The three-years system would pay better on land where natural grass grew more freely, but such land would need more working when fallowed, owing to weeds growing and distributing themselves all over. Under that system crops could never be clean.

POULTRY KEEPING.—It was agreed that it was unprofitable to allow fowls to run at will in the stables and hay yard, as they caused serious loss in the stock. Mr. Sparks favored the heavy breeds for laying and table purposes. The Leghorns were the best layers, but too small for sale. He had found that birds used to having their freedom did not do so well when shut up.

GEORGETOWN (Average annual rainfall, 18.32in.).

February 1st.—Present: seven members.

IRRIGATING FOR LUCERNE.—Mr. G. Hill read a short paper. He had just returned from Balaklava, where he had inspected the irrigation plants on two different holdings. In the first case three bores had been put down. These were all fitted with lift pumps, worked by the one oil engine. The irrigating was carried out by the means of sprinklers, the largest of which was 180ft. across, capable of watering 1½ acres of lucerne. A tank was erected at the height of about 20ft. to take any surplus water not used up by the sprinklers. He considered sprinkling the best means of watering lucerne. The lucerne was in splendid condition, and was growing at the rate of about 2ft. in three weeks. On the other holding wells had been sunk, and the water was pumped out by an oil engine into tanks erected on high stands, from whence it flowed to the sprinklers. In this instance, also, the lucerne was splendid. It was advisable to manure the lucerne with farmyard manure after each cut.

LEIGHTON (Average annual rainfall, 16in. to 17in.).

March 25th.—Present: 14 members and one visitor.

LUCERNE FOR DRY DISTRICTS.—Mr. McWaters read a paper on this subject. He said that land intended for lucerne growing should be ploughed in autumn or early winter to a depth of about nine inches, if the soil permitted it, otherwise two ploughings would be necessary, the second one stirring the subsoil to a depth of six inches, care being taken not to bring any of the clay to the surface. After being allowed to lie idle during the winter it should be harrowed and well cultivated to get rid of all weeds. A finely worked surface and seed bed could be secured by rolling and then further harrowing. Seed should be sown about the end of August or beginning of September. About 8lbs. of seed with 40lbs. of bone-dust to the acre was sufficient for this district. Barley grass, oats, and weeds germinating with the lucerne were frequently a menace to the young plants. A mower should be run over to prevent them going to seed and the cuttings left to act as a mulch to the lucerne crop. The following winter the lucerne should be harrowed, and cultivated the second year to a depth of five or six inches. In average seasons two cuttings would be obtained in addition to providing pasture for sheep and lambs. Stock should not be put on the paddocks until the crop was in flower. The best varieties of seed were Hunter River and Tamworth. A good discussion followed.

MUNDOORA (Average annual rainfall, 14.1in.).

March 29th.—Present: nine members.

SELECTING AND GRADING SEED WHEAT.—Mr. C. H. Button read a paper on this subject. He emphasised the difficulty experienced by farmers in obtaining pure seed wheat. One reason for that was carelessness in not cleaning out the machine and wheat box after drilling one kind of wheat, and before commencing the next. He did not favor selecting seed by hand, but thought that if care were taken it would be possible to obtain seed pure and true to name. He advised cleaning all seed either in the harvester or the winnower before putting it through the grader. He pointed out the great advantages of the grader for cleaning purposes, and said that it was surprising the amount of rubbish it revealed. The lower grades would do for poultry and pig feed. For wheat he favored Gluyas, and for hay Marshall's No. 3 or German Wonder. After reading this paper Mr. C. H. Button tabled five samples of wheat, showing the various stages of grading. A lively interest was awakened among members by these illustrations, and a good discussion ensued.

#### NORTH BOOBOROWIE.

December 1st.—Present: nine members and three visitors.

BREEDING MERINO SHEEP.—This subject was dealt with in the following paper by Mr. W. B. Ashby:—'I would recommend beginners to go to some reliable breeder and select some aged ewes with fairly strong wool, as strong wool denotes strong constitution. The ewes should be large framed, deep chested, with good briskets, and possibly a fold or two on their necks, down near their breasts; have broad shoulders and hips, with a good depth of thigh; and be a fair length, with straight backs, and square off at the tail. The next consideration is the selection of the ram. I would advise a very strong wool ram, very much stronger than your ewes. He should not possess weighty or very greasy wool, nor be too bulky, neither should the wool be too dry or fluffy. It should be free opening, very dense, with a good length of staple, and have plenty of character or quality, and as even as possible all over the body; in fact, you cannot have it too strong, provided you do not lose character. The ram should have a very large frame, with a clean face, soft feeling to the hand, a masculine appearance about the head, a fairly broad forehead, and horns a nice distance from the sides of the cheek bones. The head should be set on the body with a fair length of neck, with two or three good folds on it. He should have a broad and deep chest with well-sprung ribs, straight back, with good appearance behind; strong and well set legs. The period of gestation is 150 days. Sometimes at lambing the ewe needs a little help. When helping a strong ewe it is a mistake to pull the lamb right away, because the ewe, being strong, is apt to get up at once and run away, and leave the lamb. After the head and shoulders of the lamb are free the ewe should be left, and she will have no trouble in completing parturition. It is fatal to assist a ewe unless she

is straining. When a ewe shows signs of weakness, and experiences a difficulty in rising, it is wise to wait until she has lambed and then help her to her feet and walk her about until she is able to go unaided. The tailing of the lambs should be done when they are a month to six weeks old, and I prefer the knife to the searing iron. We must always retain the best of our ewes for breeding purposes. This is the fundamental basis of success. The hill is the home of the Merino, and the wool grown in the hills is of better quality than that grown on the plains, because the atmosphere of the hills is cooler, and the soil is not so salty. On no account should you overstock your farm. Sheep are of a considerable value in keeping down weeds. Two sheep well fed will give better results than three sheep insufficiently fed."

#### PORT PIRIE (Average annual rainfall, 13.2in.).

January 30th.—Present: seven members.

IRRIGATION.—This subject was dealt with in a short paper by Mr. D. L. McEwin. He urged the necessity for irrigation in this district, especially for lucerne growing. He was convinced that this fodder would grow practically anywhere, provided sufficient water was available. He would like to see trial bores put down, but as the risk of not obtaining water was too great for the average farmer to lay out the money for this work, he considered that the Government should put them down, and if they were a success, the farmers could then pay back the authorities. If lucerne had been cultivated in that district, sufficient food would have been available to carry all the stock over this period of drought. Along the River Broughton there were thousands of acres which could be successfully irrigated. The paper was discussed at some length, Messrs. J. Greig, E. B. Welch, W. Munday, O. Bond, and T. Kirchner all agreeing with the writer's remarks.

#### REDHILL (Average annual rainfall, 16.79in.).

February 25th.—Present: six members.

HEADING OF WHEAT.—Mr. W. Pengilly contributed a paper on this subject. He deplored the fact that farmers did not head sufficient of their crops, and stated that his experience this season had convinced him that headed straw was of great value for feeding young stock and more beneficial than cocky chaff because if cut at the right stage it contained a far greater amount of natural substance. He considered that five men should be able to head 17 tons daily, and advised co-operation among farmers when purchasing a machine, which should be driven by an engine. Mr. J. McAvaney agreed with the writer of the paper, and stated that the header helped to clear the land of weeds which otherwise went to seed. Mr. E. B. Holmes also contributed to the discussion.

#### YONGALA VALE (Average annual rainfall, 13in. to 14in.).

April 3rd.—Present: 10 members and one visitor.

BEEKEEPING.—Mr. F. Lambsch read a paper on this subject, and said that it was essential to profitable beekeeping to have good, well-painted hives, free from cracks. These should be provided with frames laced with brass wire, and foundations for the bees to commence work with. It was important to keep the hives free from moths, as they were very destructive. Honey should be taken in the summer, but some should always be left to provide the bees with food for the winter. Honey should never be taken at breeding times, or the young swarms would be lost. Bees were of great advantage to an orchard, and often did more good than spraying. In a good season a colony of bees should produce from 40lbs. to 50lbs. of honey. The paper was followed by a discussion.

BEAUFORT, February 4th.—HARVEST MACHINES.—Mr. W. B. Sampson read a paper on this question, and considered that for all farmers the harvester gave the most satisfactory results. The loss of the cocky chaff was compensated for by the labor saved, and when wheat was bagged it was not so liable to damage as when lying in heaps in the paddock. He favored a motor for working and pulling farm machines, as it would save the strain on the horses. It was advisable to take out all bearings after use and well wash them in kerosine before replacing. The woodwork should be oiled with boiled oil, and the whole machine kept in a weather-proof shed. A good discussion followed.

**BEETALOO VALLEY**, February 22nd.—A paper on vegetable growing was read from the *Journal of Agriculture*, and well discussed by members present.

**BOOLEROO CENTRE**, February 19th.—Mr. Wm. Michael initiated a discussion on "Preparing for Droughts." It was very essential, he said, to conserve fodder, and avoid overstocking.

**BOOLEROO CENTRE**, March 17th.—**SELECTION OF SEED WHEAT**.—Mr. F. Brooks read an interesting paper on this subject, in which he urged the importance of selecting clean wheat, free from foreign weeds, and possessing qualities suitable to the district. It was better, he said, to purchase seed from a drier climate than this, as then it would grow where moisture was scarce. He considered that it was essential to the growing of good crops to often change the variety of seed.

**CRYSTAL BROOK**, March 6th.—**Co-OPERATION**.—A paper on this question was read by Mr. W. J. Venning, who dealt particularly with buying and selling systems.

**NORTH BOOBOROWIE**, March 2nd.—**DRAINING NORTH BOOBOROWIE FLAT**.—A paper advocating this work was read by Mr. W. E. Hannaford, and was followed by a discussion.

**NORTH BOOBOROWIE**, March 9th.—**VETERINARY LECTURE**.—The Government Veterinary Surgeon, Mr. F. E. Place, B.V.Sc., M.R.C.V.S., visited the Branch. In the afternoon he gave practical demonstrations on the horse, and later delivered a lecture on "Aids to Foaling."

**REDHILL**, March 31st.—In the course of a discussion on poultry, Mr. M. M. Coffey said that fowl tick was the cause of much of the diseases among poultry. He had overcome it to a great extent by placing the legs of the fowl roosts in tins containing waste engine oil. Mr. G. A. Button considered that lucerne tended to keep poultry in good health, and to enrich the yolk of the eggs.

**YONGALA VALE**, February 20th.—**INSURANCE**.—Mr. Nancarrow read a paper on this subject, in which he strongly urged all farmers to avail themselves of opportunities to insure, not only their lives, but also their crops, stock, and implements.

## LOWER-NORTH DISTRICT.

### (ADELAIDE TO FARRELL'S FLAT.)

**BALAKLAVA** (Average annual rainfall, 16.03in.).

March 13th.—Present: seven members.

**QUANTITIES OF SEED AND MANURE TO BE SOWN PER ACRE**.—Mr. R. S. Goldney read the following paper on this subject:—"As a rule farmers use their own judgment on this question, having regard to the nature and quality of soil, and the varying nature of the seasons. But we must remember that we are dealing with abnormal conditions, and in view of the scarcity of wheat and the high prices ruling most farmers will be as conservative as possible in their sowing this year. With the later varieties of wheat sown under ordinary conditions, about 60lbs. to 70lbs. per acre if pickled, or about 10lbs. to 12lbs. less if sown without pickling is usual. With early varieties about 75lbs. if pickled, or about a bushel if sown without is recommended. With a really good germination a sowing of three-quarters of a bushel may produce a better crop than one of a bushel and a quarter with a poor germination. I believe that for this class of land, most of which has been under cultivation now for between 30 and 40 years, and is so full of weeds of different kinds, it is better to sow fairly thickly, and give the crop a better chance of keeping them down. Of course in newer and cleaner land this trouble would not be apparent to the same extent, and thinner sowings would probably give equally good or even better results. However, taking all things into consideration we shall probably endeavor to effect a slight saving in the quantity of seed per acre this year, although at the same time this will depend largely on the character of the season. With regard to manures, it has been the custom during the past few years to sow about 1wt. per acre on fallow land and about half that quantity on stubble land, this latter usually in connection with oats at the

rate of about 50lbs. of seed per acre. This season, however, as the land has not been growing much during the last two or three years, many purpose reducing the quantity to about 80lbs. per acre on fallowed land, and also slightly reducing the quantity on any stubble land which may be sown." In the discussion that followed Mr. Thomas said that this year he was going to use 70lbs. of super. on fallow land and 40lbs. or 50lbs. on stubble land. He considered that a bushel of wheat per acre would be ample this year. Mr. Reid remarked that if this season were a dry one it would be better to sow without manure. He thought that nearly a quarter of the grain was destroyed by using too strong a pickle. Mr. Burden considered that as the super. already in the ground had become somewhat insoluble it would not benefit the crops to any great extent. Members were generally in favor of this sowing.

#### BLYTH (Average annual rainfall, 16.46in.).

March 19th.—Present: 16 members.

PICKLING WHEAT.—In a discussion on this question Messrs. Pratt and Coleman were agreed that it was best to pickle wheat on the floor, and to use  $\frac{1}{2}$ lb. bluestone if the wheat was smutty, and only  $\frac{1}{4}$ lb. if not. [To what quantity of water? Mr. Zweck gives a definite strength for the solution, *i.e.*, 1 per cent.—Ed.] Mr. Zweck believed in pickling in a tub, with 1lb. bluestone to 10galls. water. The work should be done some time before seedling. Mr. J. Williams agreed with the first speakers, but generally bleached his wheat and sowed without pickling. Mr. Weland thought that pickling wheat with formalin was risky if the wheat were at all smutty.

#### CLARE (Average annual rainfall, 24.30in.).

March 21st.—Present: 12 members.

PRUNING OF APPLE AND PEAR TREES.—The following paper was read by Mr. P. H. Knappstein:—"One of the main factors in pruning a tree is to so shape it that there will be as little risk as possible of the trunk and main arms getting sunburnt, that it may easily be approached by the horses during cultivation, and that the fruit may be sprayed in a thorough manner. Pruning to produce fruit is hardly necessary in our district, and it should be more our object to reduce fruit-bearing wood, and decrease the burden of the tree. By reducing the fruit-bearing wood, it will tend to promote the quality of the resultant crop, as it will make the fruit grow larger in size, and of better appearance. Should the tree run entirely to wood it will be necessary to prune for fruit, and I would suggest that this should be done in about the month of January when the growth is almost fully developed, but not matured, when it will be entirely checked and fruit spurs developed. Summer pruning comprises cutting back laterals and converting them into fruit spurs, instead of allowing them to go unchecked, producing unnecessary wood. Furthermore I believe in the practice of allowing a tree which is running entirely to wood and which has been summer pruned to go unchecked through the winter pruning, so that the tree will have plenty to do, and so curtail its vigor. If one is starting off with a young orchard, I would recommend him to train his trees on what is known as the 'cup' system, keeping the centre entirely free from any limbs or growths, also to head his trees low. The advantages of low-heading are ease of pruning, decrease of danger from winds, and ease of spraying and picking the fruit, also the absence of risk in getting the stock of the tree sun-scalded. In order to get the trees into the shape desired it is almost necessary to start with it from the time it leaves the nursery, as it is rarely ever possible to bring a tree back to the shape required if it has been trained on another system for a few years. In choosing trees from the nursery always select those with a stem free from laterals if possible. When planting out young apple trees from the nursery I favor cutting them back to within say 15in. to 18in. from the surface of the soil, and then rubbing off all the buds below the first four or five so as to throw all the vigor into those remaining buds and obtain good growth for the head of the tree. The growth from these buds will form the main arms of the tree. The second year's pruning consists of cutting back these growths to the length required, and the resultant growth will form the secondary arms. After cutting back the main arms or first year's growth of the young tree, it is rare that more than from two to three buds on the end will send out growths, and the lower buds will send out dormant spurs which on no account should be

cut back, as otherwise you will force them into making wood which should be avoided, as it is required to cloth your tree with fruit spurs from the head or crown upward. This will ensure keeping the fruit back close to the main arms, and not out on the ends of the thin, weakly laterals, where it is liable to be blown off with the wind. If the young tree does not form fruit spurs, through cutting the first year's growth back too severely, but sends out weak laterals, I would advise leaving those laterals go untouched in the winter pruning, and then reducing them back towards the base, in the summer. For the first five or six years, I favor cutting back the leader to an outside bud so as to form the 'cup' shape that is required; after that time the grower must use his own discretion as to where to cut, and be guided by the shape he requires his tree to assume. In the case of pear trees it is almost always necessary to cut the leaders to an outside bud, as they have a tendency to grow cone shaped, which should be avoided. In some varieties of pears there is a tendency, when they reach the fruit-bearing stage, to bloom too freely, and have a very poor setting of fruit; in such cases I favor leaving the trees unpruned until they are almost in flower, and then prune them, as by so doing you practically check their vigor and stand a fair chance of them setting a good crop of fruit. In pruning apple and pear trees always see that there are no limbs crossing one another, and not too many main arms to start the tree off with." A discussion followed.

CLARE (Average annual rainfall, 24.30in.).

March 26th.—Present: 20 members.

PEAS AS GREEN MANURE.—MR. C. F. Jarman read the following paper:—"The growing of peas for the purpose of ploughing under for green manure, owing to their properties in gathering nitrogen from the air and depositing it in the soil as well as supplying humus through the decomposition of the stalks, has received wide attention at Bureau meetings. Growing peas for fodder has also had attention, and, as land becomes dearer and farms more intensely cultivated, this crop will also take a place in a modified rotation in the wetter districts of the State. Undoubtedly, they give the land a very thorough change from cereals, and the benefit of the change is, perhaps, not so widely realised as it should be. They are bad to harvest, but this will right itself as they are more widely grown. My object in writing this paper is to place before members a few facts noted last year on the growing of peas in the vineyard for the purpose of ploughing them in as green manure. The peas were sown in April, 1914, and about half an inch of rain immediately after brought them through. The rain was very light all through the growing period, but, considering the moisture was so short, the peas grew a good amount of green stuff. The vines were pruned and everything was ready for cultivation early in August. The peas, however, did not bloom until the end of September. The ground was too hard to plough them in then, and when later only light showers fell, the peas kept the ground so dry that ploughing was further delayed. It was not until the end of November, when the peas were in full pod, or such of them as had struggled to that stage, that they were ploughed. It was done very indifferently, so that the peas were never properly buried and the soil was lumpy and hard. A corner of the vineyard, where peas had not been sown, and which had been opened out with the plough early in the winter, showed splendid tilth and moisture when the plough was put in to throw it up to the vines, and looked far better than the pea-sown patch. However, strange to say, that was the very worst piece when we came to gather the fruit, in fact there was practically nothing on the vines. The remainder of the vineyard was of necessity rough, with the pea haulms not half buried, as the ploughs could not be kept in the ground. The roller and harrows were run over the land after a light shower, and the surface broken down to a fine tilth. The pea straw did not seem to block the harrows to any extent, for after it had wilted, it was easily broken up, and distributed through the soil. This saved the position to a very great extent, for every time the harrows were sent on it, the ground worked up comparatively moist, much more so than the corner that had not carried peas, and was winter ploughed and ploughed back again in the spring. The result of the harvest, although the worst we have had, showed distinctly in favor of the peas. Probably had this been done in a wet year the result would have showed to far greater advantage." A good discussion followed, members generally agreeing that peas were a valuable manure.

**LYNDOK (Average annual rainfall, 23.01in.).**

March 25th.—Present: 13 members and two visitors.

**FRUIT PACKING UNION FOR EXPORT.**—Mr. J. S. Hammat, in a paper on this subject, said that the present system of fruit export left much to be desired. There was no uniformity in grading, which led to confusion, and the extra freights and commissions were all a loss to the grower. He advised all growers who intended to export, and who lived within a certain radius of a railway to form themselves into a company or union with a central packing shed, and use one registered brand to cover all the produce. The grading of apples by machinery was necessary to secure a more even sample of fruit. The company would be their own shipping agents, and so save commission, and in the slack time could run a box-making plant. The necessary capital would be raised among the members of the company in proportion to each grower's respective acreage or number of trees, and a small percentage of the net sales could be set aside for a sinking fund from which bonuses could be paid from time to time.

**BEST WHEATS FOR THIS DISTRICT.**—Mr. W. Haese read a paper on this subject. He said that his experience proved that for hay wheats King's Early, Baroota Wonder, Tuscan, and Hugenot were the best. He advised anyone sowing more than 50 acres to sow early, mid, and late season varieties—King's Early, Baroota Wonder, and White Tuscan—in order not to have the crop ripening all at the same time. When sowing Hugenot he always mixed oats with it, as it did not stool well. For grain he preferred Marshall's No. 3 and Yandilla King, both of which out-yielded any other variety in that district. On black soil he thought it best to sow early wheats.

**NANTAWARRA (Average annual rainfall, 15.90in.).**

February 25th.—Present: nine members.

**WHITE ANTS.**—Mr. Sleep, in opening a discussion on this subject, said that his experience showed that they would destroy any kind of timber, but had a partiality for the softer varieties. As a preventive he had put a stick, saturated with blue-stone solution, into a nest of white ants, and had proved it to be effective. Charring, and timber soaked in salt water had proved failures. In dealing with verandah posts, which had become affected with the pest, he had tried boring holes obliquely and filling them with kerosine. This had had the desired effect. Mr. Smith advised painting timber with creosote as a preventive.

**CHAFF AND GRAIN PROBLEM.**—Mr. A. F. Herbert read a paper on this subject. Various methods, he said, had been tried in order to extract the grain from hay cut a little ripe. He had just put a fair quantity through a cutter and a winnower from a harvester with good results, averaging 4 tons per day. A further winnowing was usually required to get a good sample, which would probably reduce the result by two bags in every five. He considered that in any year a fair size stack might be treated in this manner with advantage, and make good feed for young stock and cattle. In discussing the paper members were generally agreed as to the advantage of this method over the header, but thought that it was necessary to feed working horses with the correct quality of chaff.

**RIVERTON (Average annual rainfall, 20.48in.).**

February 3rd.—Present: nine members.

**BENEFITS OF A SHOW TO A DISTRICT.**—Mr. Hugh Davis read a paper on this subject in which he stated that the large number of agricultural shows now held throughout the country, and the fact that the Government subsidised all money subscribed by such societies proved that they were recognised as beneficial to a district. Among the specific benefits bestowed by a show, he mentioned that it tended to encourage competition, particularly in live stock, as in these sections nothing but pure-bred stock was exhibited. He instanced the fact that a person selecting a stallion holding a prize taken in the show ring would take that as a further guarantee of its soundness. He contended that this would tend, in the near future, to improve the breed of horses and so increase their value. He applied this same argument to cattle, sheep, pigs, and poultry. Dealing with other benefits derived, he said that the opportunity given to manufacturers to exhibit their machinery, implements, and vehicles, and to set many of them in motion by means of petrol engines,

was of great benefit both to the manufacturer and the farmer, to the former because of the competition which he had to meet, and to the latter because it was possible to buy at the show, where the best was always exhibited. Referring to the grain and fodder classes a good sample of wheat tended to increase the price, and the fodder class encouraged irrigation in order to grow summer crops, and thus improved the value of good conditioned stock for the market. He stated that the Government gave a further incentive to shows by giving the Agricultural Bureaus an opportunity to exhibit their products at the Adelaide Royal Agricultural Show each year. The paper was well discussed by the members.

MALLALA, March 3rd.—The Branch was visited by Mr. L. Keith Ward, B.A., B.Sc., the Government Geologist, who delivered a lecture on underground water supplies.

TWO WELLS, March 2nd.—Mr. Pratt, in a short paper, compared the profit made from butter production, pig and calf raising, and that made from milk selling. He produced figures proving the superiority of the former. In the discussion which followed this decision was differed from by most of the members owing to the amount of labor connected with butter production.

WATERVALE, March 29th.—Mr. E. E. Sobels stated that fowls would eat grape skins fresh from the press. He believed they had certain food values, but did not think they were any use as food after fermentation.

## YORKE PENINSULA DISTRICT.

(TO BUTE.)

MAITLAND (Average annual rainfall, 20.08in.).

February 6th.—Present: 11 members.

HARVESTING WITH HARVESTER OR STRIPPER.—Mr. E. Pitcher contributed a paper on this subject, in which he said that in good seasons he favored the harvester, as the work could be done more expeditiously and the wheat was ready to be carted away as soon as possible. He warned farmers against harvesting wheat wet and stacking in a stack, as it had a very small chance of drying properly, and would consequently tend to breed weevil. In addition to this the waste was very considerable in the amount of grain that was blown over in partially threshed heads. He contended that harvesters required more attention from the driver than did the stripper, the mechanical parts being more numerous. Again, more attention to pace was necessary with the harvester, as a good deal of grain would be lost if the speed was suddenly accelerated. The life of a harvester was practically equal to that of a stripper. Dealing with the stripper he said that when using it harvesting could be commenced two or three days earlier than when using a harvester, and the grain would not deteriorate very seriously as it would be exposed to the air during the process of throwing the heap up and of cleaning. The main benefit of the stripper was that all offal was saved for future use. Even if a few heads should pass through the winnowers with grains in them it would all be heaped up and used for fodder. A further benefit possessed by the stripper was that they were built with combs that worked more satisfactorily than those of the same width on a harvester. With a stripper, less oil was used, and it took less time to oil, less horses were needed to haul them, and very little protection from the weather was required. He strongly advocated the use of both machines on a farm, the harvester to expedite the work and the stripper to contribute towards the forage supply. In the discussion which followed Mr. Tossel complained of the difficulty in obtaining experienced hands to work the harvester. He considered that with a harvester the danger from fire was accentuated, as the bags were scattered all over the paddock, while with the stripper, the grain being in big heaps, it did not take long to clear and plough a fire-break around them.

MAITLAND (Average annual rainfall, 20.08in.).

April 3rd.—Present: 10 members.

CONSERVATION OF FODDER.—Mr. E. Pitcher read a paper dealing with this question. He said that the scarcity of food at the present time proved the importance

of this matter. Farmers in that district only had themselves to blame if they were short of fodder for their stock. He strongly advised all farmers to make one or more good-sized stacks of straw. Straw should be cut, as soon after stripping as possible, with the binder, and stooked with as much care as hay, and carted to the stack as soon as convenient. When stacking every layer should be sprinkled with salt, which rendered it more palatable to the stock. If the stock were to feed at the stack he advised cutting with a grass cutter and stacking loosely, as by that means much waste would be saved. Oat straw and even barley straw should be saved in the same manner, and so afford a change of diet for the stock. Equal amounts of hay and straw, chaffed together, made a fair feed for horses that were not working too hard, and chaffed straw with a little pollard or molasses made a feed that stock could do a fair amount of work on. He further recommended saving all cocky chaff by stacking it in an enclosure of posts and wire netting some 15ft. wide and 6ft. or more in height, and roofed with straw. Ensilage was another fodder that should always be kept on hand, as its properties were most valuable in a hot and dry summer for horses or cattle.

#### YORKETOWN (Average annual rainfall, 17.47in.).

February 13th.—Present: 11 members.

QUESTION BOX.—In reply to a question it was stated that the most effective way to destroy stinkwort was to keep it fed down with sheep. Although it was not injurious to the animals, there was perhaps a danger of it tainting the mutton. Crooked breastbones in roosters was attributed to allowing them to roost on perches when young. A member who had had experience with Gratwick's Beats-all reported favorably of it. The cause of crops presenting a stripey appearance diagonally to the drilling was considered to be the irregular distribution of the seed or the manure. One member put it down to the use of slow-feed stars in the fertilizer box, whilst another stated that he had known this to occur when the old cone feed had been used.

MINLATON, March 24th.—Mr. A. Washington read a paper comparing methods of farming in this State with those adopted in Western Australia.

### WESTERN DISTRICT.

COORABIE (Average annual rainfall, 11in. to 12in.).

January 30th.—Present: 11 members and three visitors.

EXPERIMENTAL PLOTS.—Mr. H. V. Hobbs conducted experiments in the hundred of Wookata. The land in that district was typical of large tracts of country, comprising the coast ranges of the Far West Coast. The soil, which was of good depth, was sandy to sandy loam over limestone and limestone rubble, with outcrops of limestone in places. The paddock selected for the experimental plots had been cleared early in 1911, and cropped that same year and each successive year with wheat or wheat and oats, and cut for hay. Each year 55/80lbs. of 36/40 per cent. super. had been applied to the land. The land, carrying what remained of the previous year's hay stubble was ploughed with a disc cultivating plough in March, and the seed drilled on April 29th. The soil was damp enough to cause a fairly even germination, but from seeding to harvest only 10.95in. of rain fell, 4.83in. of which fell after hay-cutting, and had no material effect upon the results.

| Plot. | Area.  | Variety of Wheat. | Fertiliser.                                 | Yield.     |    | Average    |
|-------|--------|-------------------|---------------------------------------------|------------|----|------------|
|       | Acres. |                   |                                             | bush. lbs. |    | per Acre.  |
|       |        |                   |                                             |            |    | bush. lbs. |
| 1     | 1.355  | Federation        | Gratwick's Liquid Fertiliser<br>"Beats All" | 8          | 25 | 6 12½      |
| 2     | .958   | Golden Drop       | Gratwick's Liquid Fertiliser<br>"Beats All" | 4          | 38 | 4 50       |
| 3     | 1.284  | Federation        | 30lbs. 36/38 super. per acre                | 7          | 53 | 6 8½       |
| 4     | 1.240  | Federation        | 60lbs. 36/38 super. per acre                | 8          | 2  | 6 35       |
| 5     | .628   | Golden Drop       | 60lbs. 36/38 super. per acre                | 2          | 28 | 3 55½      |

Mr. E. J. Stretton conducted similar experiments at Koorngabie, but owing to lack of rain, only one plot succeeded in penetrating the surface, and that was bleached off by the hot weather when it had reached a height of only 6in.

#### GOODE.

March 3rd.—Present: 12 members.

**PRESENT SEASON'S SEEDING CONDITIONS.**—Mr. L. Will read a paper on this subject, in the course of which he remarked that in consequence of the rain experienced in that district it would be necessary to cultivate with some light implement to disturb the surface of the ground. It was not advisable to plough too deeply after a dry season, as the soil loosened itself under such conditions. Seeding should commence this year towards the middle of March, and with most of the land under crop last year which produced no return drilling would be sufficient. In reply to a question, the writer advised sowing no heavier than  $\frac{1}{2}$  bush. to the acre, although he personally was going to sow 22lbs.

#### KOONIBBA.

January 26th.—Present: 14 members and three visitors.

**PICKLING WHEAT.**—A paper on this subject was read by Mr. A. Schmidt, who advised wheatgrowers to always pickle their seed wheat. This should be done at least one week before the grain was sown, to allow of it drying thoroughly. A strong solution of bluestone was likely to destroy the germinating power of the grain. A lengthy discussion followed the reading of the paper, members generally agreeing that the best method was to shovel the grain on the floor, at the same time adding the pickle.

#### KOPPIO (Average annual rainfall, 22.40in.).

March 25th.—Present: eight members.

**THE DUTY OF THE FARMER.**—In a paper dealing with this question Mr. J. Newell said that the majority of farmers would be faced this year with an absolutely unprecedented situation, owing to the lack of water and feed. He expressed surprise that many farmers who had experienced bad years before, had not provided sufficient fodder to carry them over, and advised all to conserve as much as possible in preparation for future droughts. Now that seeding time was close at hand everything should be in readiness to begin operations. No land should be worked until it was in a fit condition, particularly if intended for wheat. Considering the high price of seed and feed, no risk should be run with the wheat crop. In his opinion every acre under crop this year should be prepared for the binder in order that the wheat might be cut and threshed. By so doing very little hay would be required, and what was grown could be cut green, so that when mixed with the straw from the header, it would be palatable to the horses. For early green feed he recommended malting barley or early varieties of wheat, which should be sown with from 2cwts. to 4cwts. of super., half of which should be drilled into the ground before sowing. Cape barley could be sown for a late crop. A sample of maize grown by Messrs. Richardson Bros. was tabled. It stood 7ft. high after 10 weeks growth.

#### MILTALIE (Average annual rainfall, 15.45in.).

March 26th.—Present: 10 members and two visitors.

**LESSONS FROM DROUGHT.**—Mr. J. W. Story read a paper on this question, and pointed out the folly of farmers, who had had previous experience of droughts, in not conserving a certain amount of hay, cocky chaff, and straw. He considered that every farmer should always carry a surplus of from 20 tons to 50 tons of hay for times of emergency. Water conservation, by dam sinking and tank building, was another important item for consideration. Much of the financial difficulties of farmers were brought about by their incurring liabilities with machinery houses, and hoping to meet them out of future crops. He considered that if farmers only used a little more forethought, and did

not embark on unnecessary expenditure, and waited, whenever possible, until the money was in hand before purchasing new machinery, the farming community as a whole would be better off. The paper was well discussed.

#### PENONG (Average annual rainfall, 11.93in.).

February 13th.—Present: nine members and one visitor.

**BEST VARIETIES OF WHEAT FOR THIS DISTRICT.**—Mr. W. Saunders opened a discussion of this subject, and said that Gluyas was the best wheat for this district. Next came Federation, and then Bunyip, and although the frost affected the latter in the hilly parts, it did well on the plains. He had had a good crop of Smarts, which had proved very good for hay, and also for grain. One variety of wheat which seemed to have been discarded was Steinwedel, which had given the best crop in his experience. Mr. O. J. Murphy remarked that it was necessary to know which wheat would resist frost and smut, and also particulars as to reaping and cleaning. Yandilla King and Tuscan were, in his opinion, the best mid-season wheats, and Rattling Jack was a good variety for a late crop, as it grew a deal of flag. If the season were early, Walkers, Yandilla King, Smarts, and Gluyas were best. Mr. C. Farrell considered that Steinwedel and Gluyas were both good wheats. The next best was Red Straw. This variety had given him big returns. It was easy to reap and clean, and stood up well. Smarts was a good wheat for hay, and was a good yielder, but Carmichael's Eclipse was hard to reap. Triumph had yielded a fair crop, but was not easy to reap, and had seemed all head. In his opinion Federation was the best for the district. Mr. A. E. Gravestock had grown Newman's for the last 14 years, and it had always turned out better than it had appeared. Last year he had grown Triumph and Solomon, but they had not yielded well. He considered that for hay Smarts was the best variety. Mr. J. Oats was convinced that Federation was the best variety for the district. He recommended experimenting with Fairbank, Thruce, and Bay Farrer, and felt that early varieties gave better results than later ones. Bayah had proved a good wheat.

#### PENONG (Average annual rainfall, 11.93in.).

March 13th.—Present: eight members and one visitor.

**CONSTRUCTION OF FARM BUILDINGS.**—Mr. J. C. Stiggrants read a paper on this subject. He said that in building the homestead it was important to select a place with a good water catchment. For the man of limited means, all buildings should be put up in such a way that additions could be made without pulling down the original. He preferred a two-storied stable of wood and iron, to accommodate 20 horses, head to head, with a loft above to hold some 10 tons of chaff. He advised building a barn of wood and iron at least 18in. from the ground, and so make it vermin proof. In the discussion which followed members were of the opinion that the scheme outlined above was too elaborate and expensive for a beginner, and were not in favor of the head to head arrangement of the stable.

#### ROBERTS AND VERRAN.

March 2nd.—Present: six members and two visitors.

**SELECTION AND PREPARATION OF SEED WHEAT.**—Mr. F. Masters, in a paper dealing with this subject, said that farmers needed to find out by tests which varieties of wheat were most suitable to the locality. It was important to have seed true to name and to prevent it becoming mixed with other varieties. Careful hand selection was necessary to secure a strong, robust, true to type seed, or failing this the grader. Experiments had shown that grains of an average development were preferable. His experience with the grader showed an increase in yield, and maintenance of stamina. Without the grader thorough winnowing to ensure all rubbish being removed, was essential. Bunt or smut could be prevented by pickling the seed in bluestone or formalin. He had found that the loss of germination was much less with bluestone than with formalin, and the loss with bluestone could be further reduced by dipping the seed in a 2 per cent. solution of lime. The bags which were to hold the pickled seed should also be pickled, as fungus frequently adhered to them, and reinfected the seed. A discussion followed. The results of experiments conducted by Mr. A. T. Cowley were

tabled as follows:—1 acre plots, drilled with  $\frac{1}{2}$  cwt. of M.L. guano super. on May 8th and 9th; 3.47in. of rain fell during growth.

| Plot. | Variety.         | Sown.            | Reaped.           | Increase<br>or Loss. |
|-------|------------------|------------------|-------------------|----------------------|
|       |                  | lbs.             | lbs.              | lbs.                 |
| 1     | Federation.....  | 76 $\frac{1}{2}$ | 52                | - 24 $\frac{1}{2}$   |
| 2     | Federation.....  | 66               | 66                | nil                  |
| 3     | Federation.....  | 52               | 82                | + 30                 |
| 4     | Federation.....  | 33 $\frac{1}{2}$ | 88 $\frac{1}{2}$  | + 55                 |
| 5     | Golden Drop..... | 34               | 97 $\frac{1}{2}$  | + 63 $\frac{1}{2}$   |
| 6     | Golden Drop..... | 47               | 109 $\frac{1}{2}$ | + 62 $\frac{1}{2}$   |
| 7     | Golden Drop..... | 71               | 100 $\frac{1}{2}$ | + 29 $\frac{1}{2}$   |

Average increase of yield over seed with Golden Drop = 51 $\frac{1}{2}$  lbs.

Average increase of yield over seed with Federation = 15 $\frac{1}{2}$  lbs.

### ROBERTS AND VERRAN.

March 30th.—Present: six members and one visitor.

**PIG RAISING.**—Mr. J. A. Buttfield read an interesting paper on this subject. He said that the uses of the pig were many—its flesh was cured for bacon and pork, the fat was melted down into lard, special leather for saddles was made from the skin, and the bristles were used for brushes. For breeding purposes it was thought best to cross the best sow produced in the district with a pure-bred Berkshire boar of suitable size and color, sound, and free from hereditary blemishes. If it was desired to establish a breed, the boar must be the same color as the sow, which should be larger than the boar. The sow should have at least 12 teats, in order to give one to each of the litter, which should consist of that number. Pigs depreciated considerably with "in and in" breeding. The little pigs became small and delicate, and decreased in number each litter, until the sow was almost barren. A sow should be 12 months old before she had her first litter, and after that should produce two a year. During breeding time she should always have a sufficiency of food, but not enough to fatten her. Her sty should be kept scrupulously clean, with a bed made of clean straw, and she should be allowed out for fresh air, exercise, and grazing an hour or so each day. The litters should arrive regularly in March and September. Pigs that were highly bred and kept growing from birth might be made porkers when 16 weeks old, but the usual plan was to leave them with the sow for nine or 10 weeks, and then feed them alone for a further 10 weeks. The cheapest and best food for pork was the small and not quite good potatoes boiled and mixed with skim milk. A small quantity of green stuff quickened the pig's appetite, and benefited its general health. A piece of rock salt in the sty was a good thing. For the pork market a pig should weigh about 100 lbs. in the carcass; for the bacon-curer, from 130 lbs. to 140 lbs. When the open sty was used, it should face the east, in order to obtain as much sun as possible. The covered portion should be a perfect shelter from the wind. Concrete floors were sometimes advocated, consisting of either lime, gravel, cinders and chalk, or Portland cement and gravel. The sty should be whitewashed at least twice a year. For successful pigkeeping cleanliness, warmth, pure air, sunlight, good drainage, and a constant variation of food were essential. A discussion followed the reading of this paper, when Messrs. S. Whittaker, W. Kunst, W. Sharman, and W. Hoar spoke.

### SALT CREEK.

March 27th.—Present: 10 members and three visitors.

**CARE OF HORSES' SHOULDERS.**—Mr. J. Rivetts read a paper on this question. He said that steps should be taken, at the first sign of a sore, to prevent it getting any worse. It was a good practice to take note of the horses' shoulders when unharnessing them. For a horse to have good shoulders it was essential that the collar should fit well, and be tight at the top. Any dirt on the collar should be removed, and the shoulders brushed to get rid of any sand or dry sweat. When ploughing, back bands should be used, to keep the weight of the swings off the horses' necks, care being taken that they did not hurt the back. The best method of curing sore shoulders, in his opinion, was to tie two soft pads, about  $\frac{1}{2}$  in. thick, on the collar on either side of the sore. He

strongly favored putting a branbag under the collar with horses liable to sore shoulders. It prevented the shoulders from scalding, kept them cool, and soaked up all sweat. A good preparation to apply to the sore was a mixture of white lead and oil. A good discussion followed. In reply to a question, members thought that for lightness of draught a wagon should be loaded heavily in front. Mr. R. Hornhardt's experience with Beats-All fertiliser had proved its equality with super., but he said that it did not prevent smut.

#### YABMANA (Average annual rainfall, 15.14in.).

March 27th.—Present: 13 members and two visitors.

IMPROVEMENTS IN FARM LIFE.—Mr. W. W. Robertson read an interesting paper on this subject, and compared city life to that on a farm. He said that the lack on a farm of many of the conveniences enjoyed by the city dweller was due very largely to want of thought. He instanced the ease with which water could be laid on throughout the house by means of a tank raised a few feet from the ground. The long hours worked on a farm were the cause of the lack of social life, but he urged farmers to let work give way a little more to pleasure whenever possible. Much of the migration of farmers' sons to the city would cease if they were given an interest, however small, in the farm, and a little more freedom for enjoyment. In the discussion which followed members generally agreed with the points raised by the writer, but thought that it was not pleasure which drew men to the cities, but the prospect of higher wages and more constant work.

#### YADNARIE (Average annual rainfall, 14.09in.).

February 24th.—Present: 20 members and a large number of visitors.

DESTRUCTION OF MALLEE SHOOTS.—Mr. A. Spriggs contributed a paper on this subject, and said that in preparing mallee land for the plough it was essential to have it clean, and to exterminate all shoots as quickly as possible. Mallee shoots should be cut and burned before ploughing, otherwise too many would be buried in the soil, and the sap from them would poison the land and prevent the growth of crops. On stubble land, where there was not sufficient straw to carry a fire to destroy the shoots, a fire rake should be used. If the rake were used in calm, hot weather 75 per cent. of the shoots and many of the stumps and roots would be destroyed. Fire raking should always be done either against or with the wind, but never with a side wind. He preferred a single row fire rake with tines close together, as the utility was greater, and the draft lighter. The best time for destroying mallee shoots was in January. A good discussion followed the reading of this paper. A paper by Mr. E. C. Stubbing on "Sowing Seed" was read for discussion at the next meeting.

#### YEELANNA.

April 3rd.—Present: 13 members and two visitors.

In reply to questions, members were of the opinion—

1. That wheat was best pickled in a cask or else dipped.
2. That the best way to prevent horses getting sore shoulders was to have a well-fitting leather collar, which, when new, had been soaked in water. It was a good plan to wash the shoulders every night with cold water.
3. That in order to remove chaff from a horse's eye the best method was to first put a twitch on the animal's nose, and then remove the chaff with a fine brush or feather. The eye should be bathed with eye lotion after the operation.
4. That 60lbs. to 80lbs. of super. gave the best results in that district.
5. That it was safe to work fallow land dry when sowing oats, as they were not subject to takeall.

CARROW, March 29th.—Mr. J. T. Beare gave an address on pickling wheat, in the course of which he described the old style of pickling with lime and salt water. For the present time he favored bluestone, pickling three bags at a time on a good floor, using the shovel system. He believed the dipping system was good, but care was necessary to see that all the grain received the pickle.

**ELBOW HILL, March 27th.**—Two papers on co-operation were read by Mr. Phillips, dealing with the co-operative purchasing of farm requisites. A discussion followed. In reply to a question as to the advisability of harrowing the land previous to drilling, members thought it wise to harrow the land now, and then again two or three days after a fall of rain.

**KOPPIO, February 25th.**—In reply to a question it was generally agreed that only a shallow working was necessary on land which had just had a good scrub burn over it. Mr. Jericho stated that he had drilled wheat into newly burnt land without any previous working, and had cut 16 tons of hay from 12 acres. It was generally agreed that rape should be sown under moist conditions.

**MILTALIE, February 26th.**—In discussing the growing of fodder for stock, Mr. W. G. Smith said that his experience showed that kangaroo grass was well suited to the district, while Mr. J. S. Jacobs considered that oats were the best food, and advocated growing the Algerian variety, as it suited the soil best.

**SALT CREEK, February 27th.**—**BREAKING IN RIDING HORSES.**—Mr. J. W. Brannack read a paper on this subject, in which he advised that a horse should be at least three years of age before handling, and recommended the use of an open bridle, a light whip, and not much work for some time. A well-girthed saddle and a crupper always gave the best results. A discussion followed.

## EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

### BERRI.

March 30th.—Present: 27 members.

**WHITE LEGHORNS.**—Mr. Hardwick read a paper on these birds, and said that he favored the White Leghorn because of its commercial value. It was a nice looking bird, and held the world's record for egg-laying. He strongly advised men starting a poultry farm to obtain their birds from a reliable man who would guarantee his stock, to use the single test pen and to breed strictly on the in-breeding system and so keep the one blood in the yard. Great harm was done, he said, both to the birds and their owners, by bringing unknown blood into the yard. In mating, care should be taken to see that the mother of the cockerel used and the hen herself, were good layers, and the resultant chicks should be as good, if not better than their parents. The hens should be two-year-old birds, and the cockerel, which should be kept by itself when not breeding, 12 months old; 10 hens to one cockerel was sufficient. The best time to bring out chicks was from the first week in July to September, as in the spring it took less to keep and rear them than in the summer. Birds hatched in July should commence to lay in December, moult early, and lay through the winter months when eggs were scarce. Birds should be penned in yards allowing 4 square feet to each bird. The yards should constantly be changed, and rape or clover seed planted in the yard thus emptied. By this means the yards were sweetened and disease kept down and the food bill lessened. Dealing with feeding, he said that young chicks did not require any food for the first 24 hours, after which oatmeal and sharp sand should be given for two days, then crushed grain and green bone. Plenty of clean water in shallow pans should always be handy. For adult birds, 2 parts of pollard mixed with 1 part bran given as a mash at a temperature of about 110 degrees for the morning meal, lucerne chopped fine at midday, and wheat at night, a little more than they required; was a good diet. He gave about 1 tablespoon of meat meal to every eight birds about three times a week. The five important things in feeding to obtain eggs were:—Lucerne, meat meal, wheat, water, and lime. As a preventive of disease it was necessary to keep everything clean. A drop of Condly's fluid in the drinking water on a hot day was a preventive of dysentery and other ailments. It was important to keep plenty of sharp oyster grit, lime, sand, and a tin containing broken charcoal.

**COOMANDOOK (Average annual rainfall, 18.01in.).**

February 8th.—Present: 13 members.

**PROFITABLE SIDELINES.**—A paper under this heading was contributed by Mr. W. LeGalley. In conjunction with wheatgrowing, he said, it would be wise to grow different fodders. The farmer could then keep a few sheep on his holding,

which were splendid for keeping down the weeds on fallow, and at the same time they added humus to the ground by their droppings. The sale of the wool and lambs would increase the yearly income. It would also be found profitable to breed a few foals to keep up the full strength of the teams. A few dairy cows were essential on every farm. He would also keep some pigs and poultry. A discussion followed. Most members' ideas were in accord with those of the writer, but Mr. Upton did not consider that the farmer on mallee country could devote sufficient time to side lines to make them return a profit.

GERANIUM (Average annual rainfall, 16in. to 17in.).

February 27th.—Present: 16 members and four visitors.

TAKEALL.—A paper on this subject was read by Mr. W. R. Goldsworthy, in which he said that takeall was very similar to smut or bunt in its development. The spore could not germinate without moisture, but after germination it would live on straw, bark, or vegetable matter for an indefinite period, though probably it would not grow to maturity unless it came into contact with a wheat root. In that case the spore would put out roots or feelers which would bore into the heart of the wheat root, causing an immediate rot. The wood tissue was eaten out, and as the spore advanced along the stem, it formed a network of filaments or fruit-bearing feelers, which at once began to bear spore pods. This continued until all the roots of the wheat plant were destroyed, and the source of nourishment for both itself and the wheat cut off. The spores of takeall were so minute and drifted so easily that if one paddock became infested with the plague the wind would soon carry them all over the district. As a curative he recommended clean fallow, with a rotation of crops—wheat on bare fallow, followed by oats, the stubble of which should be left for another year, and then bare fallow. A good discussion followed.

#### HALIDON.

March 31st.—Present: nine members and one visitor.

PLOUGH V. CULTIVATOR.—In an interesting paper comparing these two implements, Mr. O. Weste said that he intended to deal with the ordinary medium mould board share plough, and the V-shaped cultivator. The primary object in view when breaking the ground was to stir every particle of the soil. The plough was made as the best means of achieving this result. The cultivator was produced to conform to the discovery of scientists that to conserve the moisture and reduce evaporation, or the capillary action of moisture in the soil, to a minimum, the surface should be stirred, with the object of forming a mulch and breaking the capillary tubes. Two objects were in view when preparing the soil for seeding, firstly to turn the soil, and secondly to clear the land to some extent. These, of course, required a strong implement, and he believed that the plough would withstand rough usage far better than the cultivator. It was an accepted scientific fact that to enrich the soil it must be aerated, and consequently oxidised. When the under portions of the soil were exposed to the atmosphere and nitrifying bacteria, it was enriched and given those elements required for cropping. The plough, he contended, gave these chemical actions every opportunity. The cultivator did not turn, but only loosened the soil. The second object, that of clearing the land of stumps, depended on the strength of the team. Although the V-shaped cultivator, with duckfoot tines could raise as many stumps to the surface and break runners equally as well as the mould board plough, he was dubious as to its life when it came in contact with heavier and firmer stumps. It was false economy to favor the cultivator on account of its lower initial cost and the saving in team strength, as the plough would have to be used for fallowing, and the farmer who used the plough from the commencement would have his soil in better condition, and less stumps than the farmer who used the cultivator. For working the soil after rain or for the destruction of weeds the cultivator had no equal, but for the initial breaking of the soil or for fallowing the share plough was the only practical implement. In reply to questions Mr. Weste said that he favored spring release to bridle ploughs, as they were easier on the horses' shoulders. He considered an 8-furrow plough a suitable size, and did not favor disc ploughs for that district. It was decided to conduct manual tests on two farms in the district on land that had had no previous dressing of manure.

**LAMEEROO.**

January 23rd.—Present: 15 members and three visitors.

**RESULTS OF MANURIAL TESTS.**—Mr. A. J. A. Koch read a report on experiments he had conducted with various manures, and concluded that the result obtained by using Beats-all manure was so surprising and unexpected that he felt justified in continuing his experiments with it. The following table shows the results:—

| Plot. | Date of Sowing. | Quantity of Wheat per Acre and Variety. | Super. per Acre.                                      |
|-------|-----------------|-----------------------------------------|-------------------------------------------------------|
| 1     | May 22nd        | 60lbs. Marshall's No. 3 (5 acre plot)   | 85lbs. mineral super, mixed with 10 per cent. potash. |
| 2     | May 23rd        | 60lbs. Marshall's No. 3 (5 acre plot)   | Treated with Gratick's liquid fertiliser              |
| 3     | May 23rd        | 60lbs. Marshall's No. 3 (5 acre plot)   | Gratick's liquid fertiliser and 56lbs. guano super.   |
| 4     | May 23rd        | 60lbs. Marshall's No. 3 (5 acre plot)   | 100lbs. mineral super.                                |

| Plot. | Date of Sowing. | Rainfall from Sowing, in. | Date Reaped. | Date Cleaned. | Result per Acre. bush, lbs. | Total Yield of Grain per Plot. bush, lbs. |
|-------|-----------------|---------------------------|--------------|---------------|-----------------------------|-------------------------------------------|
| 1     | May 22nd        | 2.44                      | Dec. 1       | Dec. 4        | 1 15                        | 6 15                                      |
| 2     | May 23rd        | 2.44                      | Dec. 1       | Dec. 3        | 2 5½                        | 10 29                                     |
| 3     | May 23rd        | 2.44                      | Dec. 2       | Dec. 3        | 3 7½                        | 15 37                                     |
| 4     | May 23rd        | 2.44                      | Dec. 2       | Dec. 3        | 2 22½                       | 7 7                                       |

**MYPOLONGA.**

February 19th.—Present: ten members and six visitors.

**GREEN FEED.**—Mr. J. Mills introduced this subject. Rape, he said, was one of the finest fodders for winter grazing, but care should be taken to prevent the stock from bloating when turned in on the crop. A fair amount of mustard seed should be sown amongst the rape, to help prevent this bloating. Wheat was not of so much account as an early green feed. Rye should be sown at the rate of 1bush. to 2bush. per acre. It was a quick-growing fodder, and would withstand severe frosts very well. It should be fed off when young, otherwise it became very coarse. Barley and oats should be sown at the rate of 1bush. to 1½bush. per acre. The former was the better for grazing purposes, as it would stand more feeding off. A discussion followed. Some members recommended sowing King's Early wheat and barley mixed in equal quantities. Others favored Egyptian clover (berseem).

**PARILLA.** (Average annual rainfall, 16in. to 17in.).

March 25th.—Present: 14 members.

**STUBBLE BURNING.**—Mr. Moyle contributed a paper on this operation. He said that getting a fire over as much ground as possible was one of the best means of assuring a good crop. The main reason for burning stubble was to clear the way for the plough and cultivator, and to kill the mallee shoots. Fire also tended to destroy grubs, which had proved themselves a pest to wheat, particularly on the flats in that district. If the stubble was thick enough, a running fire was best, otherwise the stubble should be knocked down with harrows, using the front half only. If the fire rake was used, it should be worked either across the wind or towards it, care being taken that the fire obtained a good start, as that was a great factor in the desired success. On sandhills where the stubble was light it was best to knock down the stubble with harrows, and then fire-rake across the way it had been harrowed. The best time to commence burning was as soon as the Bush Fires Act allowed, but only on the best days, and then not too early in the mornings, as stubble always burned better about noon. The reading of the paper was followed by a good discussion, members generally agreeing with the views expressed.

## RAMCO.

February 8th.—Present: eight members and three visitors.

**FRUIT DRYING.**—The following paper on fruit drying was contributed by Mr. W. J. Green:—'Great care must be taken in the selection of trees. The main object is to produce a dried article of good size, and bright clear color, which, when graded and packed properly, will present the most attractive appearance. **Apricots (split).**—This fruit should be picked when firm and ripe. The fruit at this stage has a transparent look. It should be cut with a sharp knife, a clean cut being essential, and placed on trays 3ft. x 2ft. or 5ft. x 2ft. I prefer the former, as they can be handled by one person. The fruit should be placed in the sulphur house as soon as possible after cutting to keep it from drying off. When the house is full sulphur at the rate of 1lb. to 50 of the 3ft. x 2ft. trays should be used. Ensure a clean burn and leave the fruit in for six or seven hours or until the cups are full of juice. A number of growers take fruit out of the box with the cups dry, and the result is dark, shrivelled fruit not worth packing. When the fruit is sulphured, place it on a clean floor in a sheltered spot; and with good weather it should dry in from three to four days. When dry empty the fruit into sweat boxes, but do not place the sweat boxes in a draughty place. Peaches and nectarines are treated practically in the same way, with the exception that the peaches require 1½lbs. of sulphur to 50 of the 3ft. x 2ft. trays, and will take from five hours to seven hours; however, on a warm day they will only take from three or four hours to sulphur. Foster peaches dry out from 5½ tons green to 1 ton dry; Elberta from 4½ tons to 1 ton; Palmerston and Salway from 4 tons to 1 ton. The Zante currant is very easily dried. It is wise to see that the fruit is fully ripe before attempting to pick. Immature fruit is useless to dry. It should be spread evenly on the rack, but not too thickly, and no attempt should be made to box until the fruit is brittle and hard to the touch. A large percentage of fruit in this district is spoiled by being picked unripe, and boxed before it is properly dry; ½d. or 1d. more warrants going over the vines twice in picking, and leaving them to dry thoroughly. **Sultanas.**—I advise young growers who have never handled this fruit not to pick until a fortnight after they are ripe enough to eat, because when they are just fit to eat they are by no means fit to dry. They should be of a clear amber color, sweet, but without a trace of acidity. This means more weight and better quality fruit. Tons of good fruit are spoiled every season through lack of attention to strength, heat, and cleanliness of the dip. I have found that fruit that is exposed to the sun has a much thicker skin than that sheltered by foliage. It is best to pick the sun burnt fruit separately, as it requires a stronger dip. Use about 20galls. water to 1lb. of soda for the thin-skinned, and 16galls. of water to 1lb. of soda for the hard-skinned fruit. Dip in good open buckets, giving an instantaneous immersion in boiling lye. Test the strength with a bunch on a string, and be sure that the fruit has minute cracks but is not split from end to end. Spread evenly as quickly as possible after dipping on racks or trays. If the weather is very hot cover up the fruit, as hot weather tends to darken it. **Lexias.**—The grapes should be fully ripe. To obtain the light greenish color the fruit is picked before it gets to the amber color. This makes the five-crown raisin, but it is color obtained at the expense of weight; a good bright raisin will pay the grower better, therefore pick when the full sugar is in the grape. Dip in a boiling lye of 1lb. soda to 8 or 10 galls. of water. Strict attention to the dip and ripeness of the fruit will ensure a nice bright raisin, which should dry in from three or four days on trays, and about eight days on racks. It is important that raisins should be thoroughly dry before going into the sweat boxes, and also that swollen berries should be picked out. All fruit should be fully ripe to ensure a good quality fruit. Cleanliness is essential, for growers should remember they are dealing with food. Always have clean sweat boxes, and remember that clean, bright fruit realises more than the dark, half-ripe, half-dry fruit, and that bad fruit costs as much to dry, grade, and pack as good fruit. Use sharp knives on soft fruit and do not slip the stones. Never take the fruit out of the sulphur box until the cups are full of juice. Do not attempt to dip grapes unless the lye is boiling, and of the right strength. A weak lye will produce a dark raisin. If too strong it will split the fruit and give a sticky raisin that is hard to dry, a great trouble to the stemmer, and deficient in sugar. All fruit should be boxed in the cool of the morning or evening, and not in the heat of the day.' An animated discussion followed the reading of the

paper. Mr. Lewis disagreed with the writer in regard to using the 3ft. x 2ft. tray. He considered it too small, and favored a bigger tray. Mr. Stanley also favored the bigger tray. He used the 5ft. x 2ft. tray, and would have no other on his block. Mr. Odgers agreed with the writer, and favored the 3ft. x 2ft. tray, as it was a "one man" tray, and especially was it useful on a small block where the wife and children helped. At the same time he considered that the size of the trays to be used depended largely on the size of the sulphur box, and the labor employed. Mr. Jones favored the small tray. In reply to a question Mr. Green stated that from six to eight hours were required for sulphuring; the test was to have the cups full of juice. Mr. Odgers thought that during the middle of a hot day less time was needed than in cool weather. Some people raised the temperature of the sulphur house by burning in it prior to sulphuring, and he believed that some benefit was obtained by this. Mr. Lewis advocated picking Gordos for dipping as early as possible, as a better color would thus be obtained, and the likelihood of dealing with them in changeable weather was obviated.

#### RENMARK (Average annual rainfall, 10.93in.).

November 5th.—Present: 11 members and one visitor.

**CITRUS TREE.**—Mr. Cuttle read the following paper on this subject:—"The orange tree, with the exception of a few varieties of the mandarin, differs from other fruit trees in this respect, that after it is budded it develops into quite a differently shaped tree. Instead of growing upright, with its fruit-bearing wood hanging down like the seedling, the budded tree is inclined to sprawl over the ground. A seedling orchard will grow for 10 years without requiring any pruning, and then it is only a matter of cutting a few of the lower limbs off and the dead wood from the inside. No citrus tree should be planted that is not 3ft. high to the first limb, even if the tree has to be staked, and most of them should be, for the first year at least. In California this rule was always followed, the stakes being driven in before the buds commenced to shoot, and as they grew the laterals were pinched off, leaving the leaf at the base to shelter the trunk; these leaves, if not cut off, will give all the shade required. As the tree grows the fruit-bearing wood will hang down, and even if brushed against by horses or implements, will not split off. A worked orange tree will always come down. Another great advantage this class of tree has over a low tree is that the air and sun get well through and underneath, and help materially to check the ravages of scale. Where water floods and collects underneath low trees scale will thrive. It may be thought that the extra work and expense of raising these 3ft. standard trees would be prohibitive from a nurseryman's point of view, but the price ranges from 4s. 2d. to 7s. 6d. for year-old buds on three-year-old stock, giving a good profit. The pruning of citrus in late years has altered a lot, and not for the better; the whole insides of trees are being cut out—good live fruit-bearing wood, where the tree carries the best fruit. The oranges, not being exposed to the sun or frost, grow a thinner rind, although not so highly colored. Again, by cutting out the centre of any tree, citrus or deciduous, the outside limbs open wider. If the sun shines on the centre of an orange tree, on to the old bark, water shoots commence to grow, and the tree continues to open out wider. My advice to owners of young orchards is—Get busy before your trees come into bearing. Don't be afraid to get them up a bit; they will always come down. Some years ago the budding of lemon orchards with orange buds was much in evidence, and a bit of advice on the subject may not be out of place. Do not cut the trees back and wait for young shoots to grow, as you may, if your trees are only whitewashed, get them badly burnt with the sun. Get the orchard into condition; fertilise, if necessary; prune the trees up sufficiently high to allow of buds being put in 3ft. from the ground at least. Don't forget to cut out all thorns. The pruning should be done a month before starting to bud. The bark tightens up a few days after pruning. Spring is the best time for this work. Dormant buds are not so good, as they are apt to get overgrown with a layer of bark and wood. Select good buds; water shoots from the centre are easiest to get, but they are not as good as matured wood from the outside. Some of these water-shoot buds will produce a limb resembling an Australian navel. A bud stick, the diameter of a lead pencil, is

big enough for any limb. The budding knife must be as sharp as a razor, with a blunt point. Cut the buds with not too much wood in them—don't take the wood out; make the incision in the bark with the cross cut at the bottom, and push the bud up with the point of the blade. In deciduous budding the cross cut is usually made at the top, and the bud pushed down; it is easier, as these buds protrude more at the sides, and are liable to catch in the bark of the cross cut. Tie with string, using the thin binder twine. Care must be taken to keep the string taut as it is wound round the bud. Do not lap over the eye of the bud, but over the base of the leaf or the thorn. Keep a good hold on the string—the thick bark on the limbs will stand it. Do not irrigate for a week, and do not untie for three. If the bud is properly grown in, the base of the leaf will drop off easily when touched; if it does not, leave your strings on longer. About an inch above the live bud encircle the limb not less than half an inch wide—less would soon grow over; and as the buds grow out see that they are not broken off by the wind; keep them tied up. Sap runs better in some limbs than in others; also runs in or under the outside bark of a limb more than it does on the inside. Do not cut the old tops off for a year—the buds will do all the better—and when you cut the tops leave 18in. above the encircure to tie the buds to. After the buds have grown two years cut the stumps off level with the buds at a sloping angle. Some growers have tried sawing their trees off level with the ground, in order to get the orange seedling stock to work on, eliminating the lemon trunk; but as the shoots have a large surface to grow over they are liable to blow off. They need strong stakes, or you may take a sucker from the bottom and long-splice it into the limb you wish to keep. To do this cut the bark as if for a bud; cut the sucker on a slant, and force it in, tying it tightly. Shortly it will grow in and act as a stay." A good discussion followed.

#### WILKAWATT (Average annual rainfall, 16in. to 17in.).

March.—Present: 14 members and one visitor.

CARE OF HORSES' FEET.—Mr. H. H. Brooker contributed a paper on this subject, in which he said that young horses, running at pasture and stamping on the hard ground to get rid of flies, would soon get their feet out of shape. If one side of the hoof became worn or broken, and the toe remained long, it would cause crooked joints and bad action if unattended to. Keeping the toes short gave the correct shape to the joints, and encouraged development at the heels. If the feet were not growing evenly, or if the colt swung them in and out as it walked or trotted a partial remedy might be found in trimming the feet. He advised beginning early to handle the foal's feet, so that it soon became reconciled to the process. In that case a rasp was all that was needed, but if the colt had not been handled much during the first year the work would be better done with chisel and mallet.

SEEDING OPERATIONS UNDER PRESENT CONDITIONS.—Mr. M. A. Neville read a paper dealing with this question, in which he stated that the dryness of the soil at present was very much against good farming, and although it was early to begin seeding operations, most farmers, owing to the scarcity of feed, had had to commence, and so make the best of the feed available. In his opinion it was of no benefit to work land up again after the rain came, but better to harrow it down. The firmer the soil was the better, provided that the surface was loose. He thought oats could be drilled now with a good chance of getting early feed with the first rain that came.

#### WAIKERIE (Average annual rainfall, 8.89in.).

January 29th.—Present: 38 members and one visitor.

DRYING OF GRAPE FRUITS.—Mr. J. E. Rowe read a paper on this subject, and said that the site for the drying ground should be one that obviated heavy pulling for the horses. The most suitable position was on a slope running north and south, with a good drainage. The best method for laying out the ground was to sow with lucerne after the grading was completed. Three-quarters of an acre would be required to deal with 20 tons of fruit if the racks were used. The rack should be constructed of sawn jarrah, 4in. x 4in. for the ends, and 3in. x 3in. for intermediate uprights, and the space between the posts should not exceed 10ft. to avoid sagging. The end posts should be let 3ft. into the ground, and the intermediate posts at least 1ft. 6in. The former should be securely strutted or anchored.

If anchored the securing wires should be above ground, and attached to a large post in the ground 8ft. from the strainer. If using 4ft. netting the posts should be 4ft. 6in. apart to allow ease in stretching the netting. The top of the posts should be kept apart by 3in. x 3in. jarrah let in on top of the posts about ½ in., and secured to the uprights. The timber to strain the wires at the end of the racks should be 4in. x 3in. jarrah, giving room for the strainer to work. Fine wire should be used under the netting. The rack should be of 4ft. netting, and 2in. mesh. With four 50-yard racks all the fruit from a 15-acre block could be dealt with. The fruit should be pickled into dipping tins, and taken by means of trolley to the dip, and then run on to the racks, about 40 tins to the section, beginning at the bottom and working upwards from both sides. The fruit should not be spread too thickly in the centre, it being better to stack it thickly at the ends and edges. The best dipping buckets were shallow. The objection to water-tight dipping tins was that sand collected. Trouble in this way could be avoided by plunging every bucket into clean cold water before dipping in the caustic solution. A good idea was to put the caustic soda tins inside the dip, and the sand would collect in them, and could be cleaned out as often as required. The dip should be cleaned out every second day at least. For Gordo Blanco it should be in the proportion of 18 to 1 at the commencement of the season, and 15 to 1 as the fruit became riper. All fruit on the racks should have at least one day's sun before being placed in the sweat boxes, thus allowing the fruit in the centre to even up with that at the edges. In the discussion which followed Mr. A. E. Ross said that the chief trouble in the crystallising of raisins was that the fruit was taken off the racks before it was properly dried, which prevented the sugar drying hard. Messrs. Vasey and Dunstone also spoke.

#### WAIKERIE (Average annual rainfall, 8.89in.).

February 26th.—Present: 23 members.

WHEAT FOR RIVER DISTRICTS.—Mr. E. Jaeschke read a paper on this subject, and said that for that country Dart's Imperial was the best variety of wheat, and then Lott's and Triumph. In 1914-1915, with 2.71 points of rain, Dart's Imperial yielded 3bush., while Lott's and Triumph only gave 1½bush. and 1bush. respectively. The same year Silver Bart yielded 1½bush. On well-worked fallow, in 1913-1914, with a rainfall of 4½in., Dart's Imperial, sown with 80lbs. super., had reaped 19bush. Describing the various varieties of wheat, he said that Dart's Imperial stood up well, and gave good hay, and was easy to reap. Red Straw was a good hay wheat, but liable to red rust. Gluyas was too weak in the straw to resist wind. Yandilla King was the best hay wheat, had a tough flag, and made a nourishing food. Marshall No. 1 was a late wheat, and fair for hay. It was liable to go off during a dry spell, and was only a light yielder. Tuseau was no good in that district, as it required a stronger soil, and a more hilly country. Dealing with the preparation of fallow, he advised starting late in July, and finishing no later than August. The land should be ploughed 4in. deep, and left until the end of September, and then cultivated and harrowed. In March it should be cultivated again and sown with 1bush of wheat and 80lbs. of super. to the acre, using graded seed. If the subsoil was wet the seed should be sown dry to a depth of 2in. Thomas' manure was no good in the sandy soil of that district. Sheep were a great help to future crops.

BERRI, February 27th.—Mr. E. R. Moss read a paper on the marketing of fresh fruits, emphasising the need of great care in growing, picking, grading, and packing. For the purposes of grading and packing he advocated co-operation, in order to secure uniformity. A good discussion followed.

BOOKPURNONG EAST, February 27th.—Mr. Lyons read an article on "Smuts in Wheat" by Mr. W. McAlpine, the Government Vegetable Pathologist of Victoria. A discussion followed, in which the majority favored the bluestone pickle in preference to formalin pickle.

COOMANDOOK, March 27th.—Mr. W. Vinnis read a paper on experimental work, pointing out the great practical advantages to be gained by experiments in different conditions of farming. The discussion was held over until the next meeting to allow of its full consideration by the members.

COONALPYN, March 26th.—MISCELLANEOUS EVENING.—Various papers were read and experiences narrated. Mr. Hill read a paper on smut, and considered that the trouble could be prevented by pickling with bluestone. The spores were often spread by smut balls being broken in the drill. Members thought that if the wheat was pickled properly this danger would be overcome. Mr. G. E. Venning, referring to the boiling of corn for horses advised using a false bottom, and filling the space with water, to prevent burning.

GERANIUM, April 3rd.—Experiments conducted during the past year, owing to the unfavorable season, had mostly proved failures. Mr. W. J. Mitchell had tried dipping wheat in lime water after pickling, but could not say with what result. Mr. Norton was satisfied that liquid manure was a success as a fertilizer, but was uncertain whether it would prevent smut.

LONG FLAT, March 10th.—The Branch was visited by Mr. D. F. Laurie, the Poultry Expert, who delivered an illustrated lecture on the poultry industry. Many questions were submitted and satisfactorily answered.

MONARTO SOUTH, February 27th.—Mr. R. Hein contributed a paper on seed drills, and expressed the opinion that for rough land with plenty of stones and roots the disc drill would be most durable. For well-worked fallow land he advocated the hoe drill on account of the fact that it sowed the seed deeper with less pressure upon the hoes. He advised using a star feed distributor, as it broke the lumps in the manure, and was far easier to clean after use than a cone feed implement. Members agreed with the views of the writer of the paper.

MONARTO SOUTH, March 27th.—GREEN FEED.—Mr. J. Hartmann, in a short paper on this subject, advised giving the land a good dressing of stable manure previous to sowing. Cape barley was better than wheat or oats for green feed. It should be sown with super., after the first good rain, not less than three bushels to the acre, and the land then harrowed and rolled. For light, sandy soils rye was the best. A discussion followed the reading of the paper, and members were of the opinion that if oats were mixed with the barley it would be possible to have green feed well into the summer.

NETHERTON, April 3rd.—EXPERIMENTAL PLOTS.—The Branch decided to conduct four experiments—(1) Varieties of super., (2) different quantities of wheat per acre, (3) different quantities of super. per acre, (4) varieties of wheat.

PARILLA, February 25th.—PROVIDING AND CONSERVING FODDER FOR STOCK.—Mr. A. J. Stevens read a paper on this subject, in which he suggested that it would be wise to sow barley or early wheat for fed. He considered that lucerne, though not over profitable, was easier to grow than sorghum. He advocated cutting as much hay as possible, and using cocky chaff mixed with molasses, bran, whole or crushed oats, or pollard. He was convinced that if farming was to be made a success hay and cocky chaff must be conserved as much as possible. A discussion followed.

RAMCO, March 1st.—Members advised using poisoned wheat to get rid of sparrows and other birds that were becoming a pest. Mr. Rogers tabled samples of sultanas, one lot of which had been dipped as usual, and another lot had been sulphured. The sulphured sample looked a splendid color, but was sharp to the taste, and had evidently been picked before it was quite ripe.

WILKAWATT, March 27th.—BLACKSMITH'S SHOP.—Mr. E. Alters read a paper on this subject, and said that a blacksmith's shop on a farm was of great benefit in saving time and expense. All that was necessary was a small galvanized iron shed, an anvil of not less than 1½ cwt., a strong vice, bellows, stocks and dies, tongs, a drilling machine, a few bars of iron and steel, and a few other incidentals. Care should be taken not to build the shed too near to straw sheds in case of fire, but it should be in a convenient position for bringing implements up close for repairs. In the discussion which followed Mr. Alters favored dust coal, while other members preferred coarse blacksmith's coal for the forge.

WYNARKA, February 27th.—In reply to a question, members were of the opinion that land ploughed last December should be harrowed now and cultivated after the first rain. February and March were considered the best months to burn or cut shoots.

## SOUTH AND HILLS DISTRICT.

BLACKWOOD (Average annual rainfall, 27in. to 29in.).

March 15th.—Present: 17 members and two visitors.

**LITTLE KNOWN VEGETABLES.**—Mr. E. Ashby gave a paper on this subject, which read as follows:—The common vegetables are the garden cabbage in many varieties, the savoy cabbage, and the cauliflower, potatoes, celery, marrows, trombones, cucumbers and all that tribe, lettuces, broad beans, French beans, and all that class, radishes, turnips, carrots, parsnips, beetroot, &c. The mention of marrows reminds me that Australia has developed an extraordinary custom of letting the marrows ripen before they are cut. In England they are considered coarse and useless in that stage. If you want delicate flavor and the flesh free from granulations, cut the marrows when only one-third or half-grown. Not only will the result, when one is accustomed to it, be a greatly improved dish, but the plant will continue to produce a succession of marrows until the cold of winter stops it growth. It may not be known to all that all the varieties of cabbage, broccoli, cauliflower, kohl rabi, &c., have been derived from the same plant—a tall, stalky plant, with fleshy leaves, that I have seen growing wild on the chalk cliffs near Dover, in England. The splendid vegetables that have been evolved by the horticultural efforts of our forefathers out of the humble cabbage form one of the great tributes to human industry and intelligence. In England broccoli is grown for use in the winter; but there are two varieties, white sprouting broccoli and early purple broccoli, which form two of the staple vegetables in the spring time. I think these should be grown successfully during our cooler months. A near relative, Brussels sprouts, is, in the cooler countries, the most delicious of all the cabbage family. It is grown here a little; the difficulty is our hot and dry climate; but surely, with more care and knowledge, we could attain greater success with this splendid vegetable. Another variety of the same plant, kohl rabi, is, in England, considered of special value in dry seasons, when turnips are fibrous and hot. It should be planted in rows, 18in. to 2ft. apart, and 1ft. apart in the rows. Asparagus is extensively grown in South Australia, but sandy ground, which is not uncommon in this district, is the best of all soils for this vegetable. Each garden that has a sandy soil should have a bed. It is easily grown from seed, but takes three seasons before it is ready for cutting; but then the bed should last for many years. Sea kale is perhaps the queen of vegetables. Surely a first-class market could be made were care taken to grow it well and introduce it in the proper markets. In our dry climate it requires a little water throughout the summer months. After cutting in the spring, the small lateral shoots should be rubbed off down to one or two, so that the strength of the root may be thrown into them, and a good crown be formed for the spring. To those who are unacquainted with the treatment of sea kale I would add that it is earthed up in the winter, so that the flower and leaf stems coming through in the spring may be well bleached. It is eaten like asparagus. Chicory is another plant that grows easily in this State. Its lovely flowers may be seen in springtime along the railway banks in the West Park Lands and elsewhere. It is recommended as worth growing in a garden, as when bleached it is said to resemble sea kale, and should be cooked in the same way. Talking of roots, to my mind quite the most delicious is salsify, which produces a smallish white, carrot-like root. The roots of its near relative, scorzonera, are less pleasing to the sight, because they are covered with a black skin, which easily scrapes off. I have grown salsify for some years with varying success—sometimes it has turned out well, and at others gone to seed without forming any roots. I think, in common with most vegetables, it requires water to keep it growing vigorously. The winter, when wet and cold, seems to check it too much, and most of us have not had sufficient water for summer use. Leeks are, to my mind, much superior to onions. They want earthing up and bleaching when they are growing strongly, and will do well through our winter months. Sweet potatoes are well worth growing, as a very small patch will produce a fair supply. Some are prejudiced against them, because they are most unpleasant if boiled; but when baked they closely resemble a trombone, with sweetness added. As this plant only grows in the hot weather, a root should be saved over the winter, and sunk in a hotbed in the spring, the shoots broken off as

they come through, and struck. The household washup water should be sufficient to keep a patch going. Egg plants are first-class fried in batter; a comparatively few plants will supply a family. While we are all familiar with the large blue thistle-like flowers of globe artichokes, few of us take the trouble to grow them. In France they are much prized, and it would probably pay to get a first-class strain of seed, rather than grow the third-rate variety that is common on the roadsides of this country. Jerusalem artichokes are well known here. They are really a sunflower, and a small patch of ground, rich, and with plenty of moisture, will give sufficient tubers to keep a family supplied through the winter months. They are best when the haulm has begun to die off. There are many other vegetables that are well worthy of our attention. Large fruiting capsicums are, in the opinion of Dr. Holtze, of the Botanic Gardens, well worthy of a place in the vegetable garden. Endive, useful for salad; bore cole a hardy sprouting kale, which produces abundant sprouts of a delicious flavor about Christmas time in the Old Country; maize, or sugar corn, the heads of which are so esteemed in America; spinach, crabe or mountain spinach, New Zealand spinach, and, last, but not least, mushrooms. A mushroom bed, to those who know how, is one of the most productive of vegetable beds, and the mushroom one of the best vegetables to grow. The smallest of backyards will give sufficient room, the two conditions necessary to enable one to produce a grand return are moisture and knowledge.

---

CLARENDON (Average annual rainfall, 33.67in.).

December 7th.—Present: 12 members and one visitor.

HARVESTING AND MARKETING HAY.—Mr. E. Harper read a paper on this subject, in which he remarked that a great deal of the success of the hay crop depended on the man driving the binder. It was important to see that the sheaf carrier was on the binder and in use. Stooking should not commence until a day or so after cutting, to allow the hay to dry. He advocated a stook of from 25 to 30 sheaves, with five sheaves in the middle running to one at the ends. Marketing depended very largely on the season and the conveniences for stacking and chaffing possessed by the farmer.

HARVESTING FIELD PEAS.—Mr. L. Spencer contributed a paper on this subject, and said that the time for harvesting peas was as soon as they were dry enough to roll well. It was only waste of time to cut them when the dew was on them and when green. He advised heaping after they had left the machine, as it was more convenient for carting, and all risk was avoided of losing peas by rolling away and being thrashed out with the wind. For thrashing the roller of three or four logs was most convenient. He was convinced that providing there were sufficient hands it was most profitable to thrash while carting. He advised getting the peas into shelter quickly and cleaning them well before marketing. A good discussion followed the reading of both papers.

FOREST RANGE (Average annual rainfall, 35in. to 36in.).

April 1st.—Present: 11 members.

THE SELF-SUPPORTING ORCHARD.—Mr. H. Schultze read a paper on this subject, and said that it was more profitable to produce things needed for home consumption than those the disposal of which depended entirely on the market. He contended that an orchard would support a cow and a pig, and that the farmer would obtain the advantages from these animals with very little trouble and practically no expense. Furthermore, it was good economy to keep a vegetable garden for household purposes, and to grow a little green feed for the horse and other animals, such as barley, oats, wheat, maize, or Japanese millet.

---

HARTLEY (Average annual rainfall, 15in. to 16in.).

February 24th.—Present: 17 members and one visitor.

EXPERIMENTAL PLOTS.—Manurial tests were carried out on four plots of one acre each, sown on May 15th with 75lbs. of wheat per acre. A 50lbs. dressing of super. yielded 4bush. 2lbs., a 100lbs. dressing yielded 7bush. 8lbs., a 150lbs. dressing yielded 8bush. 27lbs., and a 200lbs. dressing gave 8bush. 34lbs.

**SEEDING OPERATIONS.**—Mr. G. Phillips, in a paper dealing with this subject, advised farmers to commence ploughing as soon as possible after the first rain in April. When weeds made their appearance the land should be cultivated and harrowed. He suggested sowing 1bush. of wheat, previously pickled, with 60lbs. of super. per acre. In the discussion that followed the reading of the paper members were of the opinion that 80lbs. to 100lbs. of super. per acre would prove a more effective dressing than the one advocated.

**STRIPPER v. HARVESTER.**—In a paper dealing with this subject Mr. B. Wundersitz said that in his opinion the stripper was the better implement, and gave the best results. Harvesters were useful when the farmer had to do all the work himself. With the stripper the crop could be taken off in less time, and work could be commenced earlier in the season than with the harvester. Mr. J. Stanton also contributed a paper on this question. He pointed out how unsatisfactory harvesters proved in sandy soil and among mallee shoots. In crops of under 4bush. to the acre they were too heavy and costly to use. Even though satisfactory on a firm soil and in a good crop there was always a loss of cocky chaff, and less acres were reaped each day than with the stripper. With a stripper and harvester of the same sized comb the stripper could be worked with one horse less, and would give a cleaner sample of grain.

#### INMAN VALLEY (Average annual rainfall, 26in. to 27in.)

March 31st.—Present: 12 members and two visitors.

**MANURES.**—Mr. J. W. Crompton read a paper on this subject, as follows:—"A manure is a substance added to the soil for the purpose of increasing or retaining its fertility and the quantity and quality of its produce. Too much nitrogen in the soil tends to make the growth rank, and wheat will dry off without developing its seed. Excess of lime or potash tends to make fodder heavier and better food. The chief foods of all green plants are phosphates, potash, and nitrogen, and carbon, which is absorbed from the atmosphere. The plant also requires a small proportion of most minerals, the chief of which are iron, lime, and salt, which are all nearly always present in the soil in sufficient quantities, with the exception of salt. The addition of salt to land tends to increase the proportion of salt in the plant. Lime is added more to sweeten the soil than to feed the plant, and so acts as a preventive of sourness. In an ideal soil, if there be such a thing, bacteria are always busy converting the humus into acids. These acids are harmful to the plant, but the lime and the alkaline matter in the soil convert these acids into direct plant foods. The application of Thomas' phosphate to the soil, and the practice of rough fallowing, also tend to sweeten the soil. The signs of sourness are the unthrifty, unhealthy condition of plants, the soil is often mossy, and when wet is usually slimy. Peas and most clovers do badly in soil that is at all sour, but melons, &c., do well, unless the acidity is very pronounced. Some grass land is improved by fire, but better still by alkaline manures. Phosphatic manures should pay well on the good grass lands of this district. Superphosphates only increase the sourness on account of their acidity, and should only be used on land that has sufficient lime in it to keep it sweet. There is a tendency in the climate of this district to produce sourness, and the soil is not rich in lime. Phosphates are the manures most required, because potash, nitrogen, &c., are almost always present in sufficient quantities in our soils. The principal phosphate manures are (1) mineral super., of which there are many brands; (2) guano, which is also nitrogenous; (3) bonedust; (4) Thomas' phosphate; (5) guano super.; (6) bone super. Mineral super. is easy to handle and drill, and is soluble in water, and in consequence is easily absorbed by the soil when wet. By mixing bonedust with Thomas' phosphate, the action of both is accelerated, and the mixture is a very good manure." The paper was fully discussed by members. Mr. R. J. Martin also read a paper on "How to combat bush fires," which was well discussed.

#### IRONBANK (Average annual rainfall, 33in. to 34in.)

February 27th.—Present: four members and two visitors.

**EFFECT OF THE HEIGHT OF WHEELS ON THE DRAUGHT.**—Mr. W. Coats read a paper on this subject. He said that this question had been the subject of recent experiments. Practical tests had been made over macadam, gravel, and dirt roads in all conditions, and also over pasture, stubble, and cultivated paddocks, with a net load in each case of 2,000lbs. The three sets of wheels that were tested were

standard size, front wheels 44in., back wheels 55in.; medium size, front wheels 36in., back wheels 40in.; and low size, front wheels 24in., back wheels 28in. It was found that wagons with wheels of standard size drew lighter than those with lower wheels, particularly on road surfaces in bad condition. Low wheels cut deeper ruts than those of standard size, and the vibration of the tongue was greater. For convenience wagons with low wheels were preferable, as those with broad tyres and wheels of standard height were cumbersome and required more room in turning. The medium sized wheels did not increase the draught in as great a proportion as the gain in the convenience of loading, and while the low wheels increased the draught far more than the convenience. On good roads lengthening the rear axle to avoid cutting ruts did not increase the draught. On sod, cultivated land, and bad roads, wagons with the rear axle longer than the front one, drew heavier than wagons with both axles the same length. Furthermore, these wagons necessitated wider gateways and more careful drivers, and were not recommended for farm use. The best form of farm wagon was one with axles of equal length, and broad tyred wheels of 30in. to 36in. in height in front, and 40in. to 44in. behind. The paper was well discussed.

#### MILANG.

January 9th.—Present: 26 members.

**HORSES.**—In a paper on this subject Mr. A. Davidson said that in breeding from mares for harness work it was essential to select a mare with pace and style, and one staunch in harness. It was most important when stinting to see that she was in good condition, and had lost her old coat. The stallion should be sound, shapely, docile, stylish, and have pace. One bred from show stock was preferable. The foal should be weaned when about six months old, and then fed on green feed and a mixture of chaff, bran, and crushed oats, and have access to plenty of water. In breaking in horses they should first be well mouthed, and then taught to lead and tie up. They were then ready to put into double harness with a quiet, reliable horse, and should be driven a short distance each day for about a week, when it would be found easy to break them in to single harness. It was advisable to wash their shoulders with cold water as soon as the collar was removed, in order to prevent scalded shoulders. He advised treating horses kindly but firmly, and stable-feeding all driving horses. Mr. A. Saltmarsh, in a further paper on this subject, said that for farming he favored the Clydesdale as being most suitable for the work. To breed a good type of roadster it was best to use a mare two removes from a draught and a pure-bred blood stallion. Horses should be broken in to harness and saddle when two years old. A good discussion followed.

#### MOUNT BARKER (Average annual rainfall, 30.93in.).

March 3rd.—Present: 42 members and one visitor.

**CARE OF LIVE STOCK ON A FARM.**—Mr. G. Cleggett read a paper on this subject, in which he said that as a farmer's interest in any part of his business was in proportion to the profits obtained, it was imperative to keep stock of a quality that would repay a reasonable amount of intelligent care, and it was inadvisable to keep old and worn-out animals. Referring to the drought, he said that it would not be altogether in vain if one of its effects was to weed out the useless stock. Dealing with the question of feeding, he remarked that the requirements of individual animals were so divergent that it was impossible to give a uniform system of feeding. In all cases feed should be given regularly and liberally, but none should be wasted; irregularity tended to cause indigestion. Idle horses and dry cows might be fed on rough food that would not be fit for workers. It was not a good practice to suddenly change the rations, but when a change was made it should be done gradually. A variety of food was always appreciated by animals. All stock should be provided with easy access to plenty of pure water, but water in the manger was inadvisable. There was not much risk attached to giving working horses as much water as they could drink before feeding, even in hot weather, provided that it was not ice-cold. Scouring was often caused by drinking before fast or heavy work. Horses needed water more often than cattle, and sheep less. Shade and shelter should be provided in every paddock, as animals felt the sudden changes in climate. The first cold rains of autumn were very trying to stock, and a little extra feed and attention at this time would often prevent serious

loss. Horses working on metal roads should be kept well shod, and if turned out for a spell the shoes should be removed, and on no account should shoes be left on mares turned out for foaling. All harness should fit comfortably, and all places likely to be rubbed periodically examined. A good wash for scalded backs and shoulders was made by pouring boiling water on wattle bark, until about the color of weak tea. No wash was effective unless applied immediately the horse was released from work. In cases of broken knees and cuts, a few applications of Stockholm tar and rest were generally all that was required to effect a cure. It was the best thing to shoot a beast with a broken leg, unless it was valuable, as a cure in such cases was very hard. It was important that all stock be seen each day, as by this means many valuable lives might be saved. The paper was followed by a good discussion.

#### NARRUNG (Average annual rainfall, 17in. to 18in.).

February 27th.—Present: 12 members.

PIGS.—A paper dealing with this subject was read by Mr. Bolger. He thought that the best pigs were the progeny of an Essex boar crossed with a Berkshire sow, as they matured quickly, and it did not take much to fatten them. Pigs of this breed should weigh from 90lbs. to 100lbs. when five months old. The best way to keep breeding sows was in paddocks of from two to three acres, securely fenced, with a razorback hog fence, and containing sheds for shelter. About a fortnight before farrowing the sows should be put into smaller pens and fed with green feed, such as lucerne, mangolds, &c. At the birth of the young pigs the sow should have as much nourishing food as possible. Barley hay was better than loose grain. The young pigs should be castrated when about a fortnight old, but not weaned until eight weeks after birth. All pigs should be given a little grain if possible, or, failing that, pollard in their drink. It was conducive to their health if plenty of charcoal was kept in the paddock or sty; this tended to prevent ricketts. A good remedy was to mix 4oz. ground ginger, 4oz. copperas, 2oz. black antimony, 2oz. saltpetre, 2oz. sulphur, and give one teaspoonful twice a day in their food. It was essential to keep the sties well aired and clean. He preferred stone sties with paved floors, with a drainage towards the front. A good discussion followed the paper.

#### PORT ELLIOT (Average annual rainfall, 20.33in.).

February 20th.—Present: seven members.

PARROT PEST.—In reply to a question as to the best methods of coping with the pest, Mr. Hargreaves said that the method he had always found effective was to sprinkle apples with strychnine and sugar.

WATTLE BARK GROWING.—Mr. Wm. Squire read a paper on this subject, in which he said that, referring principally to the South Australian broad-leaf wattle, its cultivation was easily understood. Australia was the native home of the wattles. They would grow at times and in places where little else would grow, and given a reasonably wet winter, and hot summer to follow, the sap, with the winter moisture in the top roots, would flow freely, and the bark would strip off cleanly, and finally dry out good weight to the grower, and with excellent tannic acid to the purchaser. Wattle land could be bought fairly cheaply, and if kept free of sheep, an annual return from good and fully established plantations was assured. Depots at which delivery could be made were always within reasonable distance, and a good cash buyer could usually be found. Growers were always kept in close touch with the market developments, and there was no risk in regard to market disposal. In a dry climate, particularly during a drought, the question of fires brought a dangerous element into barkgrowing. There was no sadder picture in Australian life than that of the raging bush fire devastating years of cultivation. He advised all growers to put fire breaks in their plantations. The question of fire insurance was a costly one, and with care and watchfulness it paid the grower to shoulder his own risk. Only in this State was the broad-leaf wattle found in its truest form, and it was only in this, its native habitation, that these trees reached their highest degree of purity in tannic acid, containing little or no fibre character. The only disadvantage was the fact that it had too much coloring matter when compared with the South African

bark, which, though grown from our wattle seed, had varied in character owing to difference in soil and climate. Bark should only be stripped from mature trees which ran freely, if weight and quality would be secured. The strippings should be laid out for two days' exposure before bundling them. The curling of the bark would prevent the bundles from being drawn too tight, and so preventing the passage of air, and securing perfect freedom from mould. To simplify handling, he said that bark should not be bundled in greater size than would allow at least 40 bundles to the ton. It was pleasing to note that the Commonwealth Government had placed a protective duty on wattle bark of 30s. a ton, which should be a great boon to growers. He strongly urged all bark-growers in the cultivation of wattles to carefully study the details, to strip only mature trees, always at the height of the season, bundle it into reasonably small bundles, and dry perfectly. The paper was favorably commented on.

#### PORT ELLIOT (Average annual rainfall, 20.33in.).

March 20th.—Present: seven members.

A discussion took place as to the best method of destroying parrots and other birds that had caused so much destruction in the orchards and fields this season. The general verdict was that poisoned sliced apples was the best remedy, but care should be taken to prevent children and animals getting at them. It was generally thought that now was the time to poison rabbits owing to the scarcity of feed, and that simultaneous effort was most effective. In reply to a question from Mr. McLeod *re* farmyard manure, members testified to the good returns obtained from the use of stable manure, in good conditions, but as usually there was not sufficient obtainable, superphosphates, bonedust, &c., had to be used when many acres were cultivated.

#### URAILDA AND SUMMERTOWN (Average annual rainfall, 44.35in.).

March 1st.—Present: seven members.

**POULTRY RAISING.**—Mr. H. Fleming contributed a paper on this subject, and said that about May was the best time to purchase birds to commence a poultry run with, and some half a dozen good second year hens and a vigorous cockerel should be bought. Their shed should be about 12ft. x 6ft., well drained, and in a sheltered position, with an iron roof and closed in on the weather side, but with wire netting on the remaining sides. It was well to divide the shed into three sections—6ft. x 4ft., 6ft. x 5ft., 6ft. x 3ft., and divisions 18in. high—the smaller end for roosting, and the other two for scratching and a dust bath respectively, all being cleaned out once a week. The birds should have clean water once a day, and it should always be kept out of the sun, and in a position where the birds could not pollute it in any way. Feed should be given regularly, bran and pollard mash in the morning, green feed and a little wheat at midday, and enough wheat to satisfy the birds in the afternoon. These details applied to a breeding pen. He advised using an incubator in preference to waiting for broody hens. It was best, he said, in using an incubator, to first run the machine a few days until a regular heat of 102deg. was obtained. The eggs, when put in the machine, should be attended to night and morning for the 21 days before hatching. The young birds should not be taken from the incubator until thoroughly dried, and should then be put into a lamp brooder, previously prepared. They should be fed for the first four days on Chick Vital No. 1, and then after that time a little cracked wheat could be mixed with it. When a fortnight old whole wheat might be given, but not wet mash before six or seven weeks had passed. At all times their drinking water should be kept cool, and shell grit be always available. When about 10 weeks old the cockerels should be penned up away from the pullets, and the best ones should be picked out and penned singly when they were four months old, as development would be quicker. When the chicks were old enough, if allowed the run of the garden, they would grow faster. Winter layers should be hatched early in October, and early layers and fattening cockerels in July and August.

**CHERRY GARDENS, February 23rd.**—Mr. C. Lewis, in the course of a paper entitled "Does it pay to cultivate the wattle under present conditions?" produced figures to prove that the expense attached to it rendered it unprofitable. In the ensuing discussion, Mr. Thomas Jacobs considered that a crop of wattles

improved the quality of the soil, and was always followed by a good cereal crop. He advised growing wattles on virgin soil, as on cultivated land a large percentage were often blown down by the wind or attacked by a grub peculiar to the wattle.

**CHERRY GARDENS, March 30th.**—**BEAUTIFYING THE HOME SURROUNDINGS.**—Messrs. H. and C. Jacobs read a paper on this subject emphasising the value of improving the surroundings of the homestead. They condemned all untidiness, whether it were rubbish heaps, fences in bad repair, or gates badly swung. One of the best methods of adding to the beauty of the home was to have ornamental trees and shrubs planted around. A flower garden, well-trimmed hedges, and well-gravelled and weeded footpaths, were a decided advantage. A short discussion followed.

**IRONBANK, March 27th.**—In reply to a question Mr. W. Coats thought that maize was the best crop to plant on a wet, boggy flat, and that it should be planted toward the end of September or in November.

**LONGWOOD, December 12th.**—Members thought that the dryness of the season was responsible for the great increase of insect pests. Mr. Nicholls said that by holding a tray of water and kerosine under his potato plants and shaking them he had killed off the Rutherglen fly. Mr. Blakley had rid his garden of the small green grub by flooding it with water. Discussing manures, a member was of the opinion that manures should be applied two or three months before seeding, to allow time for the manure to be assimilated by the soil.

**LONGWOOD, January 30th.**—The meeting was held at the homestead of Mr. Copley. The maize crop was inspected. Some Hickory King variety was 8ft. high, and showed to greater advantage than some Horse Tooth, which had been planted under similar conditions and at the same time. Some Craig Mitchel variety, planted later, was also doing splendidly.

**KANMANTOO, February 27th.**—**DROUGHT.**—A paper was given on this topic by Mr. A. Hay. He said that the after-effects of a drought were more serious, probably, than the drought itself. With sheep, the following year's wool clip was ruined, and horses and cattle lost so much condition that it took fully 12 months for them to recover. This drought had proved that stock did not thrive in distant pasture, as it took them too long to become acclimatised to the new conditions, and he advised either selling, even at a sacrifice, or hand-feeding stock from which a return was obtainable. He considered that after a drought the country should be lightly stocked for at least a year, in order to allow the grass to seed. The non-observance of this was the cause of the deterioration of natural pasture. He urged all to realise that there would be other droughts in future years, and advised them to prepare in advance by a systematic storage of fodder.

**KANMANTOO, April 3rd.**—An article from *Harper's Magazine*, entitled "The Real Dry Farmer," was read by Mr. R. W. Downing.

**MEADOWS SOUTH, March 3rd.**—Mr. G. T. Griggs read a paper entitled "Improve," in which he referred to the difficult conditions under which farmers worked in the early days of colonisation.

**MOUNT COMPASS, February 27th.**—As the result of experiments, members considered that by growing maize on the extensive flats for feeding green and making ensilage, the dairying industry would be greatly assisted.

**MOUNT PLEASANT, April 9th.**—The Branch was visited by Messrs. P. H. Suter and H. J. Finnis, who gave addresses on the dairy cow and Bureau work respectively.

## SOUTH-EAST DISTRICT.

**LUCINDALE** (Average annual rainfall, 23.32in.).

**March 6th.**—Present: eight members and two visitors.

**POTATO GROWING.**—A paper under this heading was read by Mr. McMorron. It was best, he said, to keep the seed in a cool, dry place, such as under pine trees or other evergreen trees of a drying nature. It was necessary to spread the tubers out thinly so as to expose them to light and heat. His experience showed that if this was done on planting the tubers would all grow and do well. He believed in planting whole seed, but if cut seed was preferred, did not advise cutting it

into a number of pieces, as it tended to leave a set with a weak eye and a subsequent delicate plant. He considered it best to take a fairly large potato and cut it in half from the crown to the stem, as this always left a strong eye in both sets. The seed should only be cut on the same day as planting, otherwise it tended to lose too much of its starch. It was not necessary to use anything to dry the cut, as a potato would dry quickly of itself. Cut seeds should always be planted in fairly dry ground, and never just after rain. He advised planting from 4in. to 5in. deep, as tubers when growing always had a tendency to rise to the surface, and with shallow planting early varieties and crops in early districts often suffered from potato grub. It was best, he said, to allow about 30in. between the rows, and from 18in. to 24in. between the sets. He emphasised the fact that manure was a great help to the potato, and thought that the superphosphate manure was the best.

**CARE OF SKINS.**—A paper on this subject was read by Mr. P. W. Dow. Dealing with sheepskins, he said that at present it did not pay to trouble about light or inferior pelts, but only with those of fair weight and quality. One important improvement he had noticed was that instead of cutting the sheep's throat, it was customary now to stick the sheep, which method resulted in a much neater skin. Care should be taken in skinning that the pelt did not get cut, as a very small cut would become a large hole when the pelt was placed in the tan. It was advisable to leave the trotters on, as they helped to keep the skin in position when drying, which should be done in a shed. It was a mistake to hang the skins where both wind and sun could reach them, as this so damaged the pelt that it became worthless. Washing was an important item in the care of skins. The handiest method for the farmer was to mix a bottle of dip with sufficient water to make it a good milk color. When this was applied it would keep weevil away, give the skins a richer color, and toughen them. This was very important, especially in summer, as skins which had not been washed became so brittle that a slight pull would tear them badly. Referring to hides, he said that the usual treatment of a hide was to pull or cut it off the beast as quickly as possible, salt it, roll it up, and let it remain so until sold. The correct method was to take it off carefully so as not to cut it, cut it off behind the ears, and not leave any ends on such as legs, &c. The hide should then be hung over a rail and washed down while yet warm, as dirt and blood were the cause of many hides smelling and being sold as tainted. The hide should then be spread out in a shed, salted well, and folded down the centre of the back so that it laid with all the points meeting. It should be left like this for about a week, and then folded up. In pegging out a foxskin the principle was to make a long rather than a wide skin. It should be begun at the fore-paws, which should be pegged to the board, and worked along the shoulders down to the hind legs, which should be drawn down a reasonable distance. The hind-quarters should then be fastened and pegged, and then the skin drawn out as wide as possible, commencing from under the arms, and working downward. The brush should always be split to the tip. Rabbit skins should be dried inside to prevent the pelt perishing and losing weight. A bow should be made of a piece of thick fencing wire, straight down the sides, flat on the top, with a loop up through the neck. The wire should be down the centre of the back and the centre of the belly, as this protected the fur.

---

#### MOUNT GAMBIER (Average annual rainfall, 32in.).

April 10th.—Present: 20 members and one visitor.

**CLEAN AND DIRTY FARMING.**—Mr. Buck, in reading a paper on this subject, said he intended to classify clean farming as that in which the binder was used, and dirty farming where a harvester or stripper were used. His remarks concerned only volcanic soil, because at Kybybolite and in that class of country the harvester was the only thing. This had been one of the hardest seasons they had experienced, and if they looked around they would see that not enough had been done for stock. They would have to go in more for saving straw, and the only way they could do this was to use the binder. Even if cattle did not eat the straw the stacks were a great shelter. In cutting wheat for hay they must have a bit of color in it. He believed in long stooks, about three sheaves wide. In cutting for grain, it could be cut about 10 days later, and the wheat would then keep a nice color. If allowed to get dead ripe for the stripper the color went from the grain. When malting barley

showed an inch of nice yellow stalk just under the head it was safe to cut it. He had been told to let barley get dead ripe, and it would bring a penny a bushel more; but he found that this did not cover what was lost through late cutting. By using the binder they could take off the crop earlier, and the weeds did not shed their seed on the ground, but came out in the "seconds," while with the harvester the crop would have to wait until it was ripe. He always picked a poor bit of land for a stack, and even when the straw was eaten the stock went there to camp, and the poor spot soon became one of the best places in the paddock. When the stacks were finished the farmer could, if he desired, cart away 50 tons to 60 tons of manure. In reply to questions, he said that he preferred White Tuscan as a wheat for any purpose in this district. Wheat should stand in ordinary weather for a fortnight after cutting, but oats less. If oats were cut too green they were bitter, and stock did not like them. His reason for preferring long stocks was because the sheaves could dry better.

#### NARACOORTE (Average annual rainfall, 22.60in.).

March 13th.—Present: 22 members.

**FAT LAMBS—THE MOST SUITABLE BREEDS AND THEIR MANAGEMENT.**—Mr. A. B. Feuerherdt read the following paper on this subject:—"In the South-East we have all the conditions necessary as far as land and climatic conditions are concerned for the fat lamb industry, but lack one essential factor, i.e., a local port and freezing works, linked up by a good system of railway to deal with the product, for it is a matter of impossibility to truck freezers to Adelaide and have them arrive there in proper freezing condition. In the first place the bloom would be entirely gone, and secondly a certain percentage would be badly bruised, and so rejected. Now the South-East, taken on the whole, is not a Merino country, nor is it an agricultural country. I am speaking more particularly of that tract of country south and west of Naracoorte right to the coast. Now it is this land particularly which we must look to to produce our fat lambs in the future. Some hundreds of thousands of acres of our richest lands are lying practically idle, little or no use being made of them whatever at the present time; deep, rich, black land, which in ordinary winters become inundated, and dry during the latter part of spring and summer, and this is the land which should be made more use of in producing summer fodder, and so fat lambs. The land becoming more fertile and more productive each year, there is practically no exhaustion of the soil, for the crops are all fed off on the land. Thus the necessary contributors, being returned for the following crop, it only needs a start to illustrate what can be done. Now, in giving you my views and opinions of fat lambs, the most suitable breeds, and their management, let it be understood that the deductions arrived at have been gathered and confined to the lower portion of the South-East after 26 years of practical experience. In connection with my brothers we have had various British breeds, and had little or no success until we tried the Romney Marsh some 20 years ago, and this breed has proved itself pre-eminently suited to the South-East and its climatic conditions, more particularly on the low-lying country of a swampy nature, and has been instrumental in maintaining the number of the flock. Its hardiness, combined with its contented disposition, symmetry of carcass, covered with a fine fleece of wool, and its exceptionally early maturing propensities, make it an ideal sheep for raising fat lambs and freezers. I advise Romney cross ewes for breeding fat lambs, but they are not easy to obtain, and to those whose intention it is to establish a fat lamb trade I recommend large framed Merino ewes and Romney rams. Let no money tempt you to part with your ewe lambs, for these are to form the nucleus of your fat lamb business in the future. You must not expect to get a result from the Merino ewe, for remember she is not a mutton breed, and is only used as a stepping stone towards what you are aiming at, and also remember that it is the ewe who has got to rear the lamb, and no ewe can do that successfully unless she is a good milker. Now, the Romney cross ewe is large framed, of quiet disposition, a wonderful milker, and carries a valuable fleece of wool that is always in demand. Any of the various British breeds crossed with Merino will also give you good ewes to mate with Romney Marsh rams, but always strive to maintain an even type to breed from, for it is only by doing so that you can expect any uniformity in your lambs. Keep your ewes in good store condition, not fat, and on fair pasture, and if they have to work for their living

all the better, providing they have not to work too hard, and keep them also well supplied with good water, and let them have access to a salt lick composed of one part sulphate of iron to 20 to 25 parts coarse salt. You will find that they will relish it, as do also their lambs at quite a young stage. Rams should be pure-bred, squarely built, have level backs, well sprung ribs, and small head (this is very important when mating with Merino ewes), and short legs. When you find a sheep answering to this description, providing that he belongs to an early maturing strain, you will have an ideal ram for breeding fat lambs. The country and climate must guide you as to the time of mating. I should advise November and December for dry early country, and January, February, and March for low or wet late country. In my opinion July and August are the best and safest months to lamb in, taking the South-East on the whole. Ewes lambing at this period will give you a better percentage of lambs, and it is not the heavy drain or tax on them as is the case with the earlier lambing. The grass, having more strength in it, helps the lamb considerably, and the ewes come in in better condition and yield a heavier clip at shearing. Rams should be left with the ewes for two months and yarded twice weekly during that period. This is very important, for it saves the rams a lot of running about, and also catches the ewes that are shy breeders. Most of the British breeds are shy workers for a start, but very vigorous when once they take to the ewes. Two per cent. of rams is quite sufficient for 100 ewes. Constant attention is necessary during the period of lambing. All dogs should be kept out of the paddock, and a pair of shears and a bottle of dip or Stockholm tar should always be ready for use on the saddle. Some ewes in lambing will throw themselves down in such a position that they are unable to rise after having given birth to the lamb, and if the paddocks are not gone over regularly and carefully in all probability both the ewe and the lamb will be lost. Having found a ewe cast, if she be badly stained, it is always advisable to shear the stained wool off and crutch her well, thus saving all risk of her becoming fly-blown. If she is stiff and her legs cramped, a little manipulation will soon restore the circulation and she will soon be able to walk away. If it is a crossbred ewe she will not hesitate in taking her lamb, but it is not always so with the Merino, and I have always found it a good plan to rub the lamb's head with the afterbirth. It sometimes happens that a lamb is falsely presented. The correct form is the two front feet first, followed closely by the nose of the lamb. Even with this correct presentation cases occur when the ewe cannot deliver her lamb; this is caused through the ram being too large in the head, or that the ewe was too small to be mated with a long-wool ram. The false presentation most common is that with one front leg tucked back. In this case the head should be gently pushed back, the hand then inserted, and the other fore leg brought forward; the delivery will then be easy. It sometimes happens that a lamb is presented tail first. In this case the hand must be passed in and the lamb turned completely round. But in my experience very little trouble occurs with crossbred ewes, the trouble being confined chiefly to the Merino ewes. When a lamb is taken from a ewe it should be rubbed about the ewe's head and nose, and placed at her head and left. Do not lift the ewe up, for in nine cases out of ten she will make off as soon as you leave her, and you may then have some difficulty in getting her to take to her lamb. Leave the two lying together and retire some distance (out of sight of the ewe if possible) and watch results. Should she get up and leave the lamb, round her up and put her with it again. This may have to be repeated several times. If this treatment fails it will be necessary for you to make a small yard and leave them there for a few hours. A month to six weeks after lambing has finished is the best time for tailing. Always choose cool, windy days if possible, and if they are late lambs it is as well to tar the cuts. I have used the searing irons for tailing, but find the tails are longer in healing, particularly in fat crossbred lambs, and so prefer the knife. A bucket or tin containing a strong solution of washing soda should be handy to the operator, and the instruments immersed in it from time to time, particularly so if any of them are dropped on the ground, thus minimising the risk of tetanus or lockjaw, and for the same reason clean yards are also necessary. I prefer splitting the purse to tipping for two reasons. It heals more quickly, and when fat (either lambs or wethers) a full scrotum improves their appearance. The lamb after being operated on should be dropped squarely on his four feet, not on his tail or ear, as is frequently the case. Bring the ewes and lambs in for marking in small mobs; the earlier the work is finished the more time will you be able to give them to mother. This is usually done by holding them in

a corner of the paddock and gradually letting them draw off. Leave the lambs with the ewes as long as you can. The choicest lamb is the one that is marketed straight from its mother. Lambs dropped in July and August should remain with the ewes until the end of the year, and wherever it is convenient always wean the ewes away from the lambs, not the lambs from the ewes. That is to say turn the lambs back into the paddock in which they have been running, for they are accustomed to that, and will soon settle down on their own. Should the lambs be taken to a fresh paddock it is advisable to run a few older sheep with them, which could be drafted off when the lambs had learnt the run of their new home. If you have a paddock sown down in the spring with a fodder crop such as rape or kale, it should, in ordinary seasons, be ready to feed off at the end of the year. Your lambs could then be weaned straight on to it. Should there be plenty of fodder available there would be no necessity to wean your lambs, for you would then find that as the lambs were marketed the ewes would not be long in fattening. Lambs, however, always fatten much more quickly than grown sheep. If the lambs are in nice fresh condition when they are put on to rape, they will become prime in from five to six weeks. But never turn any stock on to a green crop if they are empty, for it is more than probable that a percentage will become blown. Should they be empty it is advisable to give them an hour on it, and then take them off, putting them back in an hour or so, when all trouble will be over. I have had more experience with rape than most of the other summer crops, and find it gives the quickest and best results for the money spent in growing it. The one great drawback with rape is the black aphid, commonly called blight. This is always more prevalent in dry seasons, and in crops that have been sown too thickly. The more vigorous the crop the less likely are the ravages of the aphid. Keep a careful watch for it, and directly it makes its appearance crowd the sheep on it, and let them eat the plot down, for the pest, unless checked, increases with marvellous rapidity, and the whole crop may become ruined. Kale and chow mouellier are less subject to aphid than rape, and are also better winter crops. It is very necessary that stock which you intend to fatten should have access to some other feed, such as good dry grass or straw stacks, and even cutting grass rushes, and scrub are better than nothing. They will not fatten on rape alone, and must have a balanced ration." In the discussion which followed Mr. Feuerheerdt, in reply to a question, said that the wool of the Romney Marsh was more valuable than that of the Lincoln, and the quantity was from 20lbs. to 25lbs.

#### TATIARA (Average annual rainfall, 19in.).

April 3rd.—Present: eight members.

LUCERNE GROWING.—Mr. F. Satchell read a paper on this subject. He advised working the land well before sowing with harrows and rollers to get it as fine and level as possible. One cwt. of super. or plenty of stable manure worked in two or three months before sowing was a great improvement. For irrigated land 10lbs. to 12lbs. of seed with 1cwt. of super per acre was sufficient. On unirrigated land 6lbs. or 8lbs. of seed gave the best result. He considered that lucerne withstood the dry weather better than any other feed, and as it lasted for years, was the cheapest fodder to grow. Yates' Giant Upright, or Hunter River were the best varieties.

KALANGADOO, February 13th.—Discussing the question of dry bible in milking cows, Mr. Rogers said that he had had good results from using bone meal and salt.

KEITH, March 27th.—In reply to a question members were of the opinion that the best way to feed pollard to horses was one-third pollard and two-thirds bran.

KYBYBOLITE, March 29th.—A social evening was held to bid farewell to Mr. L. G. Smith on his departure to take up the position of manager of the Government Experimental Farm at Loxton.

LUCINDALE, April 10th.—A homestead meeting was held at the house of Mr. H. Langberg. A noticeable feature of the farm was the irrigation plant, worked by a 9-h.p. oil engine, drawing water from a depth of 48ft. This was used to irrigate a vegetable garden, the products of which were in splendid condition.

MILLICENT, March 9th.—A discussion took place in reference to the experimental work proposed by the department on the heavy land on the drainage area.

## POINTS FOR PRODUCERS.

### **Sheep Branding Regulations.**

An interesting point was raised at the last meeting of the Strathalbyn Branch of the Agricultural Bureau, when the following question with reference to the Brands Act was asked :—“ Where is the buyer of sheep to place his brand should his position already have been taken by the seller ? ” The Chief Inspector of Stock and Registrar of Brands (Mr. T. H. Williams) has supplied the following answer to the query :—“ The Brands Act has provided for four fixed positions for branding sheep, viz., top of shoulder, near ribs, off ribs, and rump. When a sheep brand is registered the position is fixed to one of the four authorised. Should a buyer purchase sheep which are already branded in his registered position, he must not rebrand. He may impress any of the numerals from 2 to 9 in any color paint on the back. A buyer of sheep should see that all brands are clearly shown in the sale note. The person in whose name a sheep brand is registered may brand with any of the numerals mentioned, although sheep are not branded with his registered brand.”

### **South Australian Honey.**

Reporting to the Minister of Agriculture under date London, April 1st, the Trade Commissioner writes :—“ It is to be regretted that circumstances have arisen in South Australia which prevent the shipment of any more honey here for some considerable time. Apart from the fact that it means a loss of a very valuable connection which we have spent a considerable amount of money in advertising to obtain, it also means that we are unable to avail ourselves of the exceptionally large War Office inquiries which are available at present. I received yesterday a further inquiry from the War Office for 75,360lbs., but I have not cabled the information through because of your inability to supply. There is also a shortage of honey everywhere at present, due to scarcity of freight from Jamaica. I have completed the delivery of the first 5 tons to the War Office, and am busily engaged in packing the remainder of the order at present.”

### **English Apple Season.**

“ The first consignment of Western Australian fruit came to hand in the *Moldavia* this week,” writes the Trade Commissioner under date London, April 1st. “ I took the opportunity of going through a large number of them at Covent Garden to-day. Whilst the general quality of the fruit is exceptionally good, I do not think that it is quite up to the high standard usually

shipped from Western Australia. This might be accounted for by two reasons: First, because it is the opening shipment, and naturally a little immature, and secondly because the orchards in Western Australia are now becoming older. There is, however, some exceptionally fine fruit amongst the shipment. It is to be regretted, though, that the shipment was landed in a most unsatisfactory condition, and from the appearance of some of the fruit there is every reason to suppose that, in some instances, the goods have been subjected to a temperature altogether too low. Great difficulty is being experienced by the salesmen handling the fruit in disposal, and the buyers are expressing dissatisfaction with the out-turn. Several cases of pears which I inspected were valueless, and unless the bulk of the apples is speedily put into consumption they will be in a like condition. It is extremely unfortunate that the out-turn should have been so bad, because, owing to freight scarcity from Canada, these apples arrived on, comparatively speaking, a bare market. Prices have ranged from 11s. to 15s. for the bulk of the fruit, and Cox's Orange Pippins have made as high as 25s. Apart from the actual loss to the shipper, the effect of this shipment's condition will be felt throughout the whole of the apple season, because buyers will be very cautious about operating in future shipments. Some idea of the extraordinary prices which are obtaining for superfine fruit in the West End of London will be gathered from the following list of prices, noted in a prominent shop in that locality:—

|                                 |                          |
|---------------------------------|--------------------------|
| Strawberries .....              | 12s. to 18s. per pound   |
| Navel oranges .....             | 4s. 6d. to 6s. per dozen |
| Ordinary oranges (Denias) ..... | 2s. 6d. to 3s. per dozen |
| Apples .....                    | 4s. to 6s. per dozen     |
| Pears .....                     | 6s. to 8s. per dozen     |
| Plums (Kelsey) .....            | 5s. to 6s. per dozen     |
| Grape fruit .....               | 8s. per dozen (special)  |
| Asparagus (best) .....          | 6s. per bundle           |
| Dates (fancy box) .....         | 8d.                      |
| Lemons (Messina) .....          | 1s. 6d. per dozen        |
| Pears (Doyenne de Comice) ..... | 12s. to 18s. per dozen   |

I might state, however, that these prices are the exception, and not by any means the general rule, and trade of this character is confined practically to one shop."

### **Transfer of Agricultural Bureau Members.**

Members of the Bureau, and especially Honorary Secretaries, will remember that upon the removal of a member to another district, a transfer to the nearest Branch can be easily effected. It is only necessary to apply to the Secretary of the Advisory Board, Adelaide, for the transfer, when he will make arrangements with the Secretaries concerned. If no Branch exists within reasonable distance of the new home, application should be made for the formation of a new Branch. The Board is always ready to assist in the establishment of a Branch where the need of such is felt and its possibilities are appreciated.

**Dairy Production in 1914.**

There was a great falling off in the butter production of the State for the year ending December 31st, 1914, the poundage showing a decrease of 1,708,555lbs. by comparison with the previous year, when the total produce amounted to 8,036,274lbs. The result was also a long way short of the record year (1910), when 10,717,486lbs. of butter were manufactured. The decrease in 1914 was attributable to two causes—the dryness of the season, with consequent depletion of fodder supplies and the reduction of the number of dairy cows by 16,698 head. On the other hand there were but slight decreases in the output of cheese, bacon, and ham. In fact the cheese production (2,016,085lbs.), while showing a reduction of 200,900lbs. when compared with the figures for the previous year, otherwise topped all the aggregates in the past decade. The following table, prepared by the Government Statist, shows the production for each of the last 10 years and the annual average for that period :—

| Year.                | Butter.<br>lbs. | Cheese.<br>lbs. | Bacon<br>and Ham.<br>lbs. |
|----------------------|-----------------|-----------------|---------------------------|
| 1905 .....           | 8,226,805       | 1,174,867       | Not collected             |
| 1906 .....           | 8,873,632       | 1,398,785       | 2,311,004                 |
| 1907 .....           | 8,519,340       | 1,385,790       | 3,392,162                 |
| 1908 .....           | 8,130,560       | 1,556,894       | 3,348,050                 |
| 1909 .....           | 8,482,168       | 1,578,378       | 3,741,042                 |
| 1910 .....           | 10,717,486      | 1,796,281       | 4,311,497                 |
| 1911 .....           | 9,694,666       | 1,526,930       | 3,711,064                 |
| 1912 .....           | 8,394,557       | 1,958,027       | 3,265,773                 |
| 1913 .....           | 8,036,274       | 2,216,985       | 3,254,086                 |
| 1914 .....           | 6,327,719       | 2,016,085       |                           |
| Annual average ..... | 8,540,321       | 1,660,902       | 3,424,447                 |

**Stock Slaughtered for Food and Export.**

From statistics collected from all the slaughtering establishments in the State (317), and from all farm holdings, the Government Statistician (Mr. L. H. Sholl, C.M.G., I.S.O.) has compiled a return showing that the slaughtering of animals for all purposes were less than usual in 1914. The totals include 106,200 sheep and lambs, and 17,707 cattle slaughtered for export. The following table gives the figures for the last seven years, and the annual average for that period :—

| Year.                | Sheep.    | Lambs.  | Cattle. | Pigs.  |
|----------------------|-----------|---------|---------|--------|
| 1908 .....           | 1,213,534 | 414,382 | 68,743  | 58,909 |
| 1909 .....           | 1,303,150 | 332,123 | 82,445  | 57,610 |
| 1910 .....           | 1,316,388 | 379,157 | 84,164  | 76,308 |
| 1911 .....           | 1,275,734 | 313,287 | 87,293  | 88,170 |
| 1912 .....           | 1,332,838 | 300,669 | 113,344 | 84,992 |
| 1913 .....           | 1,222,315 | 245,115 | 116,282 | 69,590 |
| 1914 .....           | 1,156,957 | 236,631 | 112,183 | 69,074 |
| Annual average ..... | 1,260,181 | 317,338 | 94,992  | 72,093 |

It will be noted that the slaughterings of sheep, lambs, and pigs were below the average, and that during the past three years the figures for cattle have remained considerably higher. The slaughterings at the Metropolitan Abattoirs in 1914 were—Sheep and lambs, 403,244 ; cattle (including calves), 52,461 (of which 2,243 were for export) ; and pigs, 15,370.

---

### **South Australian Flocks and Herds.**

The statistics issued by the Government Statist (Mr. L. H. Sholl, C.M.G., I.S.O.) show that, as was anticipated, there were considerable reductions in the flocks and herds of the State during 1914 on account of the drought. On December 31st the total number of sheep was 4,208,451 as against 5,073,057 in 1913—a decrease of 864,596, or 17 per cent. The losses ascribed to ravages of foxes, dogs, and drought were reported as 495,601, as compared with 380,869 the previous year. The number of lambs marked was approximately 824,032 from a lambing percentage of 52.09, compared with a total of 1,105,523 in 1913, when the percentage was 61.81. The ewes and lambs showed a decrease for the year of 242,255 and 281,491 respectively. The flocks in the State included 1,972,558 ewes of one year or over, and 687,628 sheep under one year. There was a decline in the strength of the herds by 52,326 cattle, the number in 1913, 352,905, being reduced to 300,579. Losses reported increased from 13,442 to 29,430. Dairy cows numbered 91,180, including 65,051 in milk, or a reduction of 16,698 on the total at the end of 1913. The number of horses dwindled from 283,641 to 267,877 head, comprising 96,058 light horses, 169,288 draughts, and 2,531 entires over 2 years old. The number of draught horses in 1913 was 177,322. In the counties horses decreased by 16,868, but outside there was an increase of 1,104 head. The mortality list showed a loss of 19,905 (of which 2,018 were boiled down at the Metropolitan Abattoirs), compared with 8,715 the previous year. There was an increase of 5,774 pigs, the numbers advancing from 64,119 to 69,893. As 69,074 were slaughtered during the year as compared with 69,590 in 1913, the improvement must be regarded as very satisfactory. The number of goats were reduced from 6,380 to 5,845, including approximately 2,030 Angoras. Other stock showed an increase of 25. Camels totalled 3,773, as against 3,783 in 1913 ; mules 915, as against 913 ; donkeys 2,638, as against 2,431 ; ostriches 1,006, as against 1,173 ; and deer 28, as against 35.

---

### **Bureau Branches Help the Belgians.**

The droughty conditions existing prior to the generous rains in May seriously handicapped the farmers, but throughout their trials they maintained a spirit of optimism and did not allow their own troubles to lessen their sympathy

and practical assistance for others in distress. Individually most of the men on the land have contributed in money or in kind towards patriotic funds raised in connection with the righteous war being prosecuted by the Allies against a pernicious Prussian military tyranny, and they have also made a ready response to appeals for assistance for the Belgian people, whose country was devastated by the ferocious hordes of the Hun as the price of their heroic resistance against a savage and overwhelming invasion. Collectively, also, the farmers connected with the Agricultural Bureau have promised more support for the starving and homeless population of Belgium. At the March meeting of the Wilkawatt Branch one member (Mr. A. Bates) intimated that he had decided to give the yield from three acres of crop at next harvest towards the relief fund. Several other members followed the example set, and as a consequence the Branch suggested that the Advisory Board of Agriculture might bring the subject before other Branches. As a result, already six members of the Claypan Bore Branch (Messrs. M. Robinson, T. Hill, G. S. Small, W. G. Webb, C. Dunstone, and D. P. McCormack) have decided to give the produce of three acres; the members of the Strathalbyn, Halidon, and Butler Branches have each devoted one acre as a "Belgian plot"; and the Booleroo Centre Branch has contributed £3 3s. in cash. This patriotic lead will probably be followed by other Branches.

### **Food Value of Molasses and Cocky Chaff.**

There is much misconception regarding the use of molasses as a food for horses. The Superintendent of Experimental Work (Mr. W. J. Spafford) writes:—"The common idea in this State is that to make a fair feed for horses with molasses all that is necessary is to mix it with water and pour it on to cocky chaff or chaffed straw. This is entirely wrong, as all rations for animals must contain a certain amount of various digestive substances. Molasses contain practically nothing that is digestible but carbo-hydrates, and as cocky chaff and straw contain very little matter that can be absorbed by the system the mixture of the two is very far from a balanced food."

### **Non-Fruiting Almonds and Marrows.**

The Horticultural Instructor (Mr. G. Quinn), in reply to several inquiries on these points, says:—"The failure of Brandis almonds to bear fruits may be due to several causes, viz., the absence of pollen from other kinds, or the absence of insects or bees to convey same to the Brandis flowers, or to unsuitable weather conditions at the time of blooming. The Brandis is a notoriously erratic fruiting almond, and in consequence is unsatisfactory

to plant for nuts. The trees—or at least some of them—could be budded over to other sorts which do not bloom so early, and consequently escape the rough wintry weather which usually occurs at the time the Brandis blooms. The best sorts grown by local nurserymen are Hatch's Nonpareil, Ne Plus Ultra, White Nonpareil, Peerless, I.X.L., Stockham's Papershell, and Jose's Seedling. Of these kinds the White Nonpareil and Peerless bloom along with the Brandis, but the others are later. If the trees are to be budded they should be cut back to a few stumps in the winter, and the buds inserted during next summer into the young shoots whenever buds are procurable and the bark will lift on the stock shoots. The non-fruiting marrows may be due to only male blossoms opening upon the plants, or at any rate no female flowers being open at the same time. As the sexual elements are produced in separate flowers they must be transferred from male to female to secure fertilisation of the bloom. Without fertilisation there is no melon fruit. The absence of insects may also account for the non-setting of the marrows. Artificial fertilisation may be carried out when the pollen is shedding by rubbing the pollen vessels in male blossoms into the stigma of the female flower."

### **Ration to Fatten Cattle.**

"What is a fair ration to fatten a beast," is a question submitted by a correspondent at Meadows South. The Government Veterinary Lecturer (Mr. F. E. Place), in reply, says:—"Speaking generally, it is essential in fattening an animal to give more food than the system requires, so that it may store the excess as meat. Housing, quietude, rest, all add to the speed with which the animal lays on fat. At the commencement the nitrogenous ratio of the feed should be 1 : 7, and later 1 : 5.5. An ideal food should be composed of the following percentage:—Proteids, 9.40; fat, 2.15; carbohydrates, 55; non-nutritious, 33.45. To produce 1lb. live weight 12.5lbs. of such a dry food would be required. This result would be brought about by a daily feed of 3lbs. cake, 3lbs. meal,  $\frac{1}{4}$ cwt. green feed or roots, and 12lbs. straw, taking the components of the feed to be of average quality."

### **Advantages of Grooming Horses.**

The Veterinary Lecturer (Mr. F. E. Place), in reply to a question from a Rockleigh settler, writes:—"Horses regularly groomed are more easily kept in condition than those which are not, because the skin removes more waste from the body than the bowels and kidneys, and grooming enables

this to be done with less expenditure of energy. Some years ago observations were made for a series of years on a large stud, and it was found that groomed horses required less oats to do the same work than ungroomed, and the daily saving in oats was 2lbs. per horse—an economy worth carrying out in a stud of over 3,000 animals. To obtain this advantage the whole body should be lightly currycombed, then gone over with the dandy brush, then with the body brush, and finished off with the rubber. The performance should be repeated after work. Of course, such a toilet is not practicable under South Australian conditions of farm labor.”

---

### **Effect of Dehorning.**

In an experiment with 10 cows at the Kansas Agricultural College it was found that for the first five days after dehorning the cows lost an average of  $\frac{1}{2}$  lb. of milk per day. At the end of the fifth day they began to return to their normal flow, and in a few days eight of them were giving a substantial increase. The greatest gain was with the cows that had been hooked and driven away from their feed previous to the dehorning. The two that did not increase in production were the “boss” cows of the herd. Cattle that are dehorned before the coming of warm weather and flies usually heal without any trouble. Much time and trouble is saved by dehorning the calves with caustic potash. This should be done before the calf is a week old, or a stumpy horn will develop which will have to be removed later with clippers or saw. Scrape the button or young horn with a knife until it is red. Then moisten it and rub it well with a stick of caustic potash, or with household lye, being careful not to get it in the skin around the horn, as it is very irritating there. This should be repeated in a few days if a deep scab does not form in the centre of the horn.—*Farmers' Gazette*, October 23rd, 1914.

---

The value of any variety of olive depends chiefly on its recoverable oil content; its fruit-bearing capacity and habit; its constitution and immunity from disease; and its ability to thrive under the prevailing conditions.

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

## STOCK INQUIRIES.

Replies Supplied by Mr. F. E. PLACE, B.V.Sc., M.R.C.V.S.,  
Veterinary Lecturer.

"W.G.," Tailem Bend, has a yearling filly with head and neck swelling, foul breath, and a slimy discharge from the mouth.

Reply—The symptoms are those of severe poisoning by worms. It will be necessary to steam the head with a teaspoonful of eucalyptus oil in steam, and to rub warm fat or embrocation into the swollen neck. Give in the drinking water twice a day for three days 1oz. hypsulphite of soda, and then, if recovery sets in, a dessertspoonful of Fowler's solution of arsenic in food daily for a fortnight.

"A.H.," Manoora, asks for the titles of practical works on veterinary science and the horse, suitable for a blacksmith.

Reply—Law's *Farmer's Veterinary Adviser* will probably meet requirements; for the horse only, Hane's *Veterinary Notes for Horse-owners*; and for shocing, Fleming's *Principles of Horseshocing*.

"A.G.T.," Moorook, has a horse with small hard lumps on the back near the saddle and on the neck under the collar. He also inquires the treatment for mare troubled with cough, jugular pulse, soft swellings, and lassitude.

Reply—1. The knife will remove the lumps—other things won't. 2. The asthma is complicated with heart trouble, as indicated by the lassitude and jugular pulse. Probably little can be done, but 15 drops of Tr. digitalis three times a day on the tongue may give some relief.

"G.J.B.," Renmark, has a young horse so thin-skinned that he galls at the girth in spite of every precaution.

Reply—Tie the girth back so that it does not get under the elbow, and wrap a bit of woolly lambskin round it. Thoroughly clean the sweat off the elbow after work every time, and dress with Tr. arnica loz., meth. spr. 1 pint, a little two or three times a day, which will probably relieve the trouble.

“A.W.L.,” Eden Valley, has a sluggish colt suffering from a swelling of the lips and cheeks.

Reply—The symptoms are compatible with blood worms. The treatment usually recommended is a dose of castor oil,  $\frac{1}{2}$  pint, with a similar amount of warm milk in a drench once, then a dessertspoonful of Fowler’s solution of arsenic once a day in feed for a fortnight.

“C.H.,” Forster, reports the death of a colt one year nine months old. The symptoms were sudden severe colic and food matter returned through nose and mouth, with difficulty in throat.

Reply—Bloodworms and long round worms are the trouble, and the symptoms of the first point to a ruptured stomach, due probably to worms boring in that organ. Treatment:—Half a pint each of castor oil and milk once as a drench; then a dessertspoonful of Fowler’s solution of arsenic once a day in the food for a fortnight. Also a teaspoonful of sulphate of quinine once a day either in food or smeared with molasses in the mouth for a fortnight, at the same time as the arsenic.

The Mallala Branch asks:—Is it advisable to give kerosine to horses troubled with worms?

Reply—Kerosine is sometimes spoken well of for worms, but the writer has seen too much lung trouble follow its use to be able to conscientiously recommend it. It is a good mechanical purgative, and  $\frac{1}{2}$  to  $\frac{3}{4}$  of a pint is a fair dose for a horse.

“T.Y.,” Wynarka, forwards the hock-joint of a horse which died from injuries received from barbed wire entanglement. He asks the cause of death.

Reply—The lower end of the tibia exhibits a scrofulous ulceration of the bone, which probably arose from injury to the trophic nerves as a result of the accident.

“G.E.R.,” Greenock, has two old mares falling off in condition and a light horse passing blood and long round worms.

Reply—Worms are at the bottom of the mischief. The two poor mares would not benefit by turpentine and oil, but the light horse might if due care is exercised in the drenching. It would probably

be better to let each one have two tablespoonfuls of Fowler's solution of arsenic once a day in the food for two or three weeks. The old mares would also be better to have a teaspoonful of sulphate of iron once or twice a day for a similar period.

"J.T.M.," Spalding, reports that a three-year-old filly has a ruptured navel (umbilical hernia), which frequently gets hard and causes pain. She has developed a general pasty swelling under the belly and breast.

Reply—The hardening of the rupture occurs through food staying in the part, which is analagous to the human appendix. It is probable that surgical treatment would not be satisfactory, which it would have been up to two years. The present pasty swelling is due to worms.

"K.F.," Hundred of Mantung, complains that a draught mare has swollen hind legs, and a light mare (4yrs.) is lame off hind leg from discharge at fetlock of several weeks' standing.

Reply—1. Probably there is no danger in the condition, which points to lymphangitis, or failure to remove waste from the body. She would be better for light work, and should receive twice a day in her chaff a flat tablespoonful of a mixture of  $\frac{1}{2}$ lb. each of sulphate of iron, sulphur, saltpetre, resin, and 1lb. of linseed meal. 2. The trouble most probably arose from a stake in the first instance, and has now probably reached the stage when a dressing twice daily of pure iodine, one dram (as much as will lie on a shilling) to a pint of methylated spirit, will effect a cure. Should the swelling start again, it would be well to give her a teaspoonful of saltpetre in feed twice a day for a few days.

"W.H.U.," Colton, has a light mare (8 years), which has had two foals, low in condition, slobbers, and makes a choppy noise when eating. She is much tucked up, tires very quickly, and seems to have been strained. She is fed on sheaoak, and gets water once a day.

Reply—Possibly there is something wrong with her teeth, but more probably it is a case of sheer debility, and additional food and water are required. Improvement would probably follow the administration of a tablespoonful of the following powder twice a day in the feed of chaff:— $\frac{1}{2}$ lb. each of sulphur, sulphate of iron, gentian, liquorice, and 1lb. of linseed meal.

"W.N.," Meadows South, reports that his cow suffers from stiffness, grunts when moving about, and has difficulty in eating. She slobbers, and her tongue seems paralysed.

Reply—It would be well to report this case to the Chief Inspector of Stock, Adelaide, as it may be a case of tuberculosis or actinomycosis of the throat and chest. It may also be many other things, and it would be necessary to see the animal to form an opinion.

Monarto South Branch reports the death of sheep, some fed on sheaoak and others on wheaten chaff. Symptoms—Sheep lie down, and will not eat. After death a “jellyfish” fluid is found underneath the skin just below the jaws. When the carcass is lifted up a light yellow fluid runs out of the mouth.

Reply—Unless flukes are found in the liver, the disease is of a braxoid nature, due to *bacillus transudationis malignae*, and the Government Veterinary Lecturer would esteem the favor of a carcass recently dead being sent to him, preferably to arrive on a Friday, so that he may make a *post mortem*. The carcass should be well packed in a packing case, so that fluid cannot escape, and sent, carriage forward, by passenger train. Treatment is extremely difficult in these times, because constant change of paddock is required, the sheep being changed every three days at least, and the paddock being given a week or ten days’ chance to get rid of the infection before they come on it again. In the case of those being hand fed, sulphur, saltpetre, and sulphate of iron will be taken in the feed at the rate of an ounce of the mixture, which is of equal parts, to every 10 sheep once a day. Sometimes bleeding of the eye vein will give a sheep a chance of recovery.

“R.E.J.,” Parrakie, has—(1) Two colts with swollen sheaths; (2) a sleepy mare that urinates frequently; (3) horses that eat dung; and (4) an old mare with swell under belly.

Reply—Blood worms. The treatment for all is a teaspoonful of saltpetre twice a day in feed for a few days. Then, for No. 1, give a tablespoonful of Fowler’s solution of arsenic in feed once a day for a fortnight; for No. 2, 3, and 4 give two tablespoons of Fowler’s solution for a fortnight, stop for a fortnight, and repeat for a third fortnight, working the horses if seed has arrived.

“H.J.C.,” Naracoorte, has a stallion with a foot burnt around the heel and the top of the hoof.

Reply—First poultice, with a teaspoonful of tr. arnica in the poultice, for a few days, renewing every day; then dust with boracic acid twice daily, and if recovery is very slow paint with spirits of iodine twice daily (iodine 1 dram, methylated spirit 1 pint). Watch carefully to see that matter does not under run the frog and sole, as if it does drainage must be made near the point of the frog.

The Crystal Brook Branch asks—(1) If bluestone placed in the drinking water is a protection against bloodworms, and (2) the treatment for horses swollen in the upper lip, which froth blood from the nostrils, and invariably die within a few days.

Reply—(1) Some people have great faith in bluestone in the drinking water as a preventive of bloodworms—incidentally, the writer has not; the quantity usually prescribed is 1—10,000, or 1lb. per thousand gallons. (2) The symptoms are common to many diseases, and a diagnosis could not be made without seeing them. There may be some poison weed, such as euphorbium or gyrostemon, which would cause the symptoms. Moulds in chaff would also do it. As a preventive give molasses, and, if attacked, milk.

“C.A.E.,” Verran, has an aged mare suffering from general doughy swellings.

Reply—Probably the result from stings of March flies, causing breaking down of blood cells. Work lightly, and give a teaspoonful of saltpetre twice a day in feed for a week or so.

“Y.T.S.,” Yuna, W.A., has a Clydesdale mare which had a cold, with cough and nasal discharge; this soon ceased, but the animal now has great difficulty in breathing.

Reply—It is to be feared that the mare has become broken-winded after the attack, which might have been bastard or inward strangles. Try a wineglassful of linseed oil in the feed once a day.

“E.P.Y.,” Undalya, has a draught brood mare which fell away in condition after weaning. She had not responded to treatment for worms.

Reply—It is impossible to say what is the matter with the mare, but a tablespoonful of the following powder once a day in her feed for a fortnight or so may improve her:—Equal parts of sulphur, sulphate of iron, saltpetre, gentian, powdered liquorice, and linseed meal.

“R.A.G.” asks treatment for mare suffering from pain in the belly.

Reply—The changing of feed is the main cause of the trouble, and no doubt worm complications also exist. It would be well to give a little molasses with the millet chaff, also 1oz. per horse per day of sulphur in feed. This is a heaped tablespoonful. When the pain comes on a warm drench of coffee or spirit of wine will relieve.

“J.G.G.,” Spalding, has a horse suffering from nasal gleet, with distortion of the face, softening of bone, and a discharge of stinking pus from one nostril.

Reply—To effect a cure, surgical operation by qualified veterinary surgeon is necessary (trephining). Any treatment without this is not likely to do much good. Mix 1oz. tincture *hydrastis canadensis* in half a pint of methylated spirits and half a pint of water, and syringe 2oz. of the mixture into the nostril morning and evening. This may relieve the symptoms somewhat, in which case follow by blowing in once daily a powder made of 1 part calomel and 5 parts boracic acid, a pinch at a dose.

“N.M.A.A.,” Coonawarra, has a pony with swelling under belly caused by collision with plough handle.

Reply—The swelling is due to bruise effusion, and will disappear. An occasional fomenting with hot water will help, as will also dressing it twice a day with tincture *arnica* 1oz., water 1 pint. This quantity will last for a week or 10 days. The swelling will have probably disappeared long before that.

“H.G.P.,” Rockleigh, asks the method of drenching for sand.

Reply—Back horse into a corner, put loop over nose behind tusks, if any, and throw slack over beam or raise on fork till there is a slight fall on back of tongue. If very obstreperous put twitch on nose. This is not often wanted. Tickle roof of mouth with fingers of left hand and put neck of bottle against roof of mouth. Let go a few drops on to tongue, which should be free. Natural swallowing will set in, then a wineglassful will be readily swallowed, then another, and so on. Do not pinch the throat or hold the nostrils. and so on. An ordinary beer bottle is a very satisfactory implement for the purpose, and is put into the mouth just in front of the grinder teeth. Many horses take the milk and honey mixed with their chaff, and do not need to be drenched. A sand powder which may be given once a day for a week or so consists of a dessertspoonful of sulphur, one of cream of tartar, and one of baking soda. This is mixed dry in feed. Rubbing of the belly is very helpful.

“H.L.C.,” Salisbury, has a mare with chippy and dry hoofs.

Reply—The cause of the trouble is the continued dry weather acting on hoofs that lose their natural moisture too quickly, and become brittle. Now that the rain has come, let her stand in clay pug for a few hours daily. Before going a journey well rub in a mixture of mutton fat and Stockholm tar (half and half) melted together.

“J.R.H.,” Watervale, has a five-year-old mare which chokes and coughs when eating.

Reply—Swollen throat. Rub with liniment or turpentine outside, and steam with a teaspoonful of eucalyptus oil or turpentine as

often as convenient. Put a rag dipped in Stockholm tar on the bit, and leave it in the mouth for a few hours at a time.

"M.O.W.," Halidon, submits four questions.

Replies—(1) Mixture of black antimony, sulphur, and saltpetre, is a very old and good alternative. It is generally prescribed to be given in food once or twice a day for a week or so. About a tablespoonful of the mixture is a fair dose. It should not be given continuously, but with intervals of a week or so. (2) What benefit do horses derive from sulphate of iron in the trough? Is a teaspoonful to 40galls. too much for daily use? The drug is supposed to be a tonic. In the water it kills the larvae of worms. An ounce to 40galls. would not be at all too much, and would have a better effect. It can be used continuously, but a cheaper and better form of iron is freshly perhydrated oxide, which results from letting the water run through old scrap such as bolts, &c., kept in the trough. (3) How much crushed linseed is needed per day per horse to give the best results? As the horse does not require much oil in his food, 2oz. to 4oz. are likely to give better results than a larger quantity daily. In cases of debilitating sickness the quantity may be increased and given boiled as jelly. (4) Horse died from enteritis (?), had laudanum, ether, and sweet nitre. What should treatment have been? If really enteritis, a bullet; otherwise a fresh sheepskin over loins, tincture aconite 10 drops hourly, bleeding at jugular, and later stimulants, such as coffee, ammonia, &c.

"L.R." Halidon, has a horse with round bare patches on its body. They do not itch, and no parasites are visible.

Reply—Probably ringworm. Dress daily with a mixture of 1 part benzine and 3 parts olive oil. Possibly it is eczema, in which case give a tablespoonful of sulphur in food daily as well.

"A.T.," Yadnarie, has a medium draught colt which suffers from intermittent colic, goes off feed for stretches, and looks round at his flanks.

Reply—The symptoms are those caused by the migrations of bloodworms, which have set up chronic irritation of the large bowels, resulting very likely in the formation of calculi or balls in the bowels. Put him on bran mash only for two days, then give a physic ball of 6drs. aloës (obtainable of the local chemist). When the scouring has ceased give tincture nux vomica 10 drops twice a day on tongue for a fortnight. For worms use Fowler's solution of arsenic.

"E.C.L.," Yadnarie, has a pony mare which gets over a rail and rubs her belly.

Reply—A symptom of sand. Try milk and honey in the feed.

“E.J.C.,” Wanbi, asks for a remedy for sand.

Reply—From a pint to a quart of milk and a pound of honey are warmed up together, and either given as a drench or mixed with feed. Many horses take it readily in the latter way. The dose may be repeated in a few days if thought necessary.

“C.A.L.,” Naracoorte, has an aged mare which is suffering from the following symptoms:—Colic in afternoon, but was kept at work for an hour longer; then passed water, but became stiff and trembled all over as she returned to the stable; then continued to strain to pass water, lay down but did not roll, became very hot, ears cold, trembling increased, belly swelled and became drum-like; careful getting up and down, bending of back and head to one side. P.M.—Bladder empty, sand in bowels, which were much discolored. The mare was a fast eater, and had a large drink of water after midday meal.

Reply—The case began as one of flatulent colic arising from working after drinking after a meal, then probably strangulation of the blood vessels of the bowel set in, and possibly a twist of one of them. When showing pain, the mare should have been stopped, and her flanks and belly well rubbed, the hind bowel emptied, and a stimulating drench given such as sweet nitre, or gin with peppermint, or a tablespoonful of mustard put on the tongue. It is not a safe plan to try and work off a fit of colic; it answers sometimes, but in others assures a fatal ending.

“E.W.P.,” Edillilie, has a horse that suffered from bowel irritation caused by bad water and probably blood worms. First treatment was chlorodyne 1oz., water 1 pint every four hours. Soft food.

Reply—The treatment probably relieved the symptoms. Water contaminated with decaying vegetable matter is undoubtedly injurious to horses. It should be roughly filtered or the dam precipitated with lime or bluestone. Probably 4oz. of Epsom salts will be beneficial given in food every Saturday.

“E.W.P.,” Koppio, has a stallion, 10 years, which, after receiving eight tablespoons of turpentine in a bottle of oil, has been unable to withdraw his penis, which for 10 weeks has been swollen and exuding serum.

Reply—The dose of turps. was four times too big, and was undoubtedly the active agent in causing the trouble, which has by this time become chronic and difficult to deal with. Sling the organ by a broad band round the loins, bathe frequently with warm water in which a little washing soda has been dissolved—a handful to a bucket—and give a teaspoonful of powdered camphor in a little

molasses on the tongue twice a day for five or six days; this latter will spoil him for work as a stallion, but as he is already rendered useless it will not matter much. If he recovers it would be beneficial to have him castrated.

"C.H.B.," Mundoora, had a horse which, treated for sand with 30 drops tincture nux vomica, scoured, moped, and died.

Reply—30 drops of tincture nux vomica would not move sand, nor would it cause scouring in an ordinary way unless repeated frequently.

"A.C.H.," Franklin Harbor, reports the death of a mare from lockjaw. He describes post-mortem conditions.

Reply—Worms may have been the cause of tiny wounds in the bowels, into which the tetanus germs found their way, but it is more probable there was some small external wound which would not attract notice while the post-mortem was being made. The most successful treatment of lockjaw is to treat any visible wound with spirit of iodine and keep the animal quiet, allowing green food or sloppy mash which it can suck up, and as much Epsom salts in these or the drinking water as it will take (generally about eight ounces a day).

"W.J.H.," Karoonda, has a mare affected with sand.

Reply—Give a quart of new milk and a pound of honey warmed together. If she will not take it with chaff give as a drench. Turn on back and rub belly well with a rail. After give twice a day on tongue 10 drops tincture nux vomica for a week.

"F.C.K.," Victor Harbor, has a horse, seven years, which, during damp weather at intervals loses use of right hind leg. The leg is stiff, and drags for some steps, then goes all right, sometimes for 12 months, and then will remain stiff for 18 hours or more.

Reply—The complaint is probably due to thrombosis of the right iliac artery, the main blood supply of the leg being cut off by the blocking of the vessel, which has most likely been brought about by the migrations of blood worms. If this is the case no treatment will be of much use, but when the trouble is acute frequent fomentation of the leg with hot water or putting a fresh sheepskin over the loins may minimise the stiffness.

"E.A.M.," Murat Bay, has a buggy horse, nine years, which eats dung, and after going a few chains at work roars as if his windpipe was cut, and drops from suffocation. He makes the same noise when starting to eat, paws the ground, puts his nose up in the air, opens his mouth as if trying to get breath, then swallows and seems

to gargle at back of throat. He has been relieved by Stockholm tar, and especially by steaming with eucalyptus, after which he eats the oil and bran and seems much easier.

Reply—The trouble lies in the neighborhood of the larynx, or top of the windpipe. It is difficult to say what is the exact cause without examining the beast, but supposing that it is some common cause, such as laryngeal catarrh, he will be much relieved by steaming and receiving three times a day 10 drops of tincture belladonna in a little honey smeared on his teeth. Rub the outside of his throat with white oils or liniment once a day, and steam, but do not use more than a teaspoonful of eucalyptus at a time. With this treatment he will improve, but if it is a tumor growth only surgical treatment would be of any avail.

“W.H.A.,” Saddleworth, has an aged gelding with the following symptoms:—Hard, painful swelling on right jaw and throat; keeps head up, and does not like to work jaws; opens lips wide and keeps teeth shut; and sometimes a clicking noise is audible near jaw; in other respects he seems all right.

Reply—The symptoms are those of fractured jaw, and the treatment would be to feed on slops and give Nature a chance. Later turn out in green feed.

“L.R.W.,” Arno Bay, had a pony mare with a cut in foot. He dressed the wound with spirits of salts, put on a leather pad, and turned the animal out. Lockjaw developed, though the pony can suck up green stuff and slops, and take Epsom salts in slops.

Reply—Spirits of salts are an idiotic dressing for a wound. Try them on a cut finger and see. Lockjaw or tetanus is produced by germs which are always present in the soil, getting a foothold in a suppurating wound in which there is no free access of air. They produce poisons which affect the great nerve centres through the blood. Convulsive contractions of all the muscles follow, hence the flicking of the third eyelid over the eye. The popular name lockjaw arose from the muscles of the jaw being more markedly affected than others on account of physiological peculiarities. From its nature the disease can be transmitted to other animals with open wounds, either inside or outside of their bodies. Prevention lies in disinfection of the place the patient is in. Under the treatment adopted a continuance of the Epsom salts should be followed by recovery in a few weeks. In future the wound should have immediate attention, and be kept open and clean. Stockholm tar is a better dressing than HCl.

"E.W.W.," Murat Bay, has a horse, four years, which slobbers when feeding, and is losing condition.

Reply—The trouble arises from teething. He is cutting his last four molars. Mix with the feed twice daily for a week as much grey powder (mercury and chalk) as will lie on a sixpence, and relief will follow. Green and soft feed is advisable for a few weeks and no heavy-work.

"T.S.," Forster, asks if the bones of an animal poisoned with strychnine would retain sufficient poison to kill other animals.

Reply—An animal killed by strychnine remaining long enough for bones to bleach, would not be likely to poison another, but if phosphorus were used changes take place which sometimes leave the bones a potential source of poison.

"S.H.L.," Peake, has a horse whose mouth and tongue get perfectly dry after a little work. The gums are very soft.

Reply—The horse has some subacute feverish ailment, such as gastritis, probably arising from worms. Give him a tablespoon of the following powder once a day in his feed for 10 days or a fortnight—equal parts of salt, sulphur, Epsom salts, baking soda.

"A.H.T.," Cleve, has a medium draught gelding, rising four years, whose purse swells up, breaks and discharges, and gradually refills.

Reply—The colt is most probably suffering from schirrous cord, which means that certain germs called botriomyces gain access while the castration wound is open, and cause the trouble. It is difficult to get rid of without a further operation to remove the affected cord, but the following treatment may be tried:—A teaspoonful of iodide of potassium in the feed once a day for three or four weeks, but stop if the hair falls off the body. Touch the wound lightly where it occurs with a lotion made of 1 part sublimated iodine and four parts pure carbolic acid. This is a very strong caustic, so use with care, and mind fingers.

"B.W.," Hartley, has a two-year-old filly which scours, is off feed, and has a swelling between off eye and nostril.

Reply—The swelling is a dental trouble, and the scouring, &c., is probably due to the same cause. If green grass is available let her have it. As much grey powder (mercury and chalk) as will lie on a threepenny-bit once a day for a week will help; afterwards a flat teaspoonful of sulphate of quinine twice a day for a week. Both drugs may be mixed with a little molasses and smeared on the tongue.

"A.E.G.J.," Naracoorte, had a filly, two off, which grew very weak and was shot. The liver was apparently a mass of white matter.

Reply—The mass of matter in the liver was a hepatic abscess, the result of so-called bastard or inward strangles. Should a similar condition be suspected, ounce doses of hyposulphite of soda for a week or two may do good, but tonics, such as sulphate of quinine, will also be required.

“P.H.C.,” Julia, asks if drinking muddy water is injurious to horses.

Reply—There are many objections to muddy water for horses, such as mechanical impaction from indigestible mud, embryo worms, vegetable poisons, and so forth. Bluestone is often recommended to clear the water. It may be used as strong as 1—1,000, but is probably effective at 1—10,000. Chloride of iron, 1—10,000 is safer and better. Precipitating the mud by throwing in quicklime and letting it settle is useful, but a pump and filter bed attached would soon pay for themselves in improved health.

“A.R.P.,” Rhine Villa, has horses in poor condition which tremble in shoulders, later tremble all over, at work show distress in breathing, recover on resting, but appear foundered by tucking hind feet under them. They are fed mouldy lucerne hay.

Reply—There is little doubt that there is chronic digestive trouble, which is rendered more acute by the mouldy forage, and matters will probably get worse instead of better. Boil the worst of the hay. Give molasses with the other, and mix two tablespoons of syrup of phosphate of iron with feed twice a day for a fortnight. Give also a handful of bonemeal in one feed a day. Put Stockholm tar on the hoofs of the worst.

“S.H.C.,” Cherry Gardens, had some cows in fair condition die. A post-mortem showed that the animals were apparently healthy. At first they lost power of limbs and loins, but their appetite remained good. Others are sick.

Reply—Although the bibles are not dry, the disease is what is somewhat absurdly called dry bible. It is akin to scurvy or berri berri, and arises not from want of food, but from lack of certain constituents in the food which can only be supplied by green feed or change of diet. Preventive treatment should be licks consisting of four parts bonemeal and one part saltpetre. If the cows do not take to it as a lick, a handful may be put in the mouth once a day. Give two tablespoons of syrup of phosphate of iron once or twice a day on the tongue for those showing symptoms, and continue for a week, or longer if necessary. For those that are down give a pint of yeast and a gallon of milk daily, care being taken not to choke them. Shoot those which are beyond recovery.

"J.J.M.," Hart, reports the death of a foal whose bowels were tightly packed with round white worms (*Ascaris megalocephala*).

Reply—Sometimes thousands of these will tightly pack the bowel, as described, and are frequently prescribed for. An occasional dose of castor oil (half-pint), will cause them to shift. When so numerous they actually poison the beast.

"M.C.," Spalding; "C.H.C.," Wirrabara; "J.G.D.," Talia; "P.C.P.," Wirrega; "F.L.," Mundoora; "C.," Mundoora; "A.E.H.," Warrow; "W.J.H.," Meadows South; "O.B.," Koolunga; Monarto Branch; "W.L.W.," Keith; "A.A.L.," Keith; "H.H.," Mundoora; "C.T.L.," Overland Corner; "Paddy," Mallala; "A.F.H.," Nantawarra; "W.N.," Glencoe East; "W.J.H.," Karoonda; "H.J.D.," Black Springs; "C.K.," Morehard; and others have described the symptoms of horses suffering from blood worms and blood-worm poisoning.

Reply—For full information see the article on "Blood Worms" in the May issue of the *Journal*. Points to remember regarding the use of Fowler's solution of arsenic (liquor arsenicalis B.P.) are:—This is not a drench; its administration is in the food once daily; one tablespoon for a colt; two tablespoons for a horse; give once daily for a fortnight; stop for a fortnight; repeat for a third fortnight.

Replies by Mr. C. A. LOXTON, B.V.Sc., Government Veterinary Surgeon.

"Farmer," Koppio, asks treatment for:—(1) A five-year-old gelding with a reddish lump the size of the yolk of an egg on one side of the purse; (2) whether it is dangerous to give horses sulphate of iron immediately after treatment with arsenic? and (3) can the sulphate be given alone or with powdered gentian?

Reply—(1) The gelding has schirrous cord. This condition is due to infection of the end of the spermatic cord after castration. The best treatment is surgical removal. After carefully cleaning and disinfecting part, the growth should be dissected away from the surrounding tissues, and the cord cut above the growth, preferably with an emasculator. It may respond to treatment with iodine. Paint swelling daily with tincture of iodine. If possible, inject about a tablespoonful of same into substance of growth with a syringe. Give internally every day a teaspoonful of iodide of potash dissolved in a little water and mixed with bran. (2) There is no danger in giving sulphate of iron with Fowler's solution, but as it would render part of the arsenic insoluble, it is better to give separately. A day's interval would be sufficient. (3) It may be

given in feed or in water as preferred. It is probably better taken in the feed. There is no necessity to combine it with gentian, except that the mixture makes a better tonic.

"M.P.C.," Yeelanna, inquires the treatment for a working horse which is weak and sluggish, perspires freely even in cold weather, is stiff in the joints in the mornings, and is slightly constipated.

Reply—Put the horse out of work for a few days, and give Epsom salts 1oz. and saltpetre 1 teaspoonful daily in mash. Follow with light work, and give a mixture in feed of raw linseed oil  $\frac{1}{2}$  pint, lime-water  $\frac{1}{2}$  pint. About half a cupful twice daily in feed will suffice.

### HORTICULTURE.

Replies supplied by Mr. G. QUINN, Horticultural Instructor.

"G.J.B.," Remark; wants to kill tamarisk trees growing on a channel bank.

Reply—Bore as many auger holes as the solidity of the stump will allow, and fill them with kerosine. Plug the holes with clay.

"G.D.M.," Whyte-Yarcowie, forwards cauliflower leaves affected by pests, and asks for a remedy.

Reply—The specimen of cauliflower leaf is affected by the well-known aphid which attacks the brassica family of plants, which include the cabbage, cauliflower, turnip, rape, mustard, &c. This pest is killed by spraying with either tobacco and soap wash, kerosine emulsion, or resin wash. These remedies are more effective if applied fairly hot. It is a good plan before planting out autumn cabbages and cauliflowers to dip the young plants thoroughly in one of these compounds. The holes in the leaf are, I believe, caused by the larvæ of the diamond-backed cabbage moth, although none are present on the material forwarded. These are active little green caterpillars, which drop suspended on a web when alarmed. They pupate usually in a thin, light, silvery cocoon, fastened to the ribs and veins of the leaves. These pests may be killed by the use of the remedies suggested for the aphid, but the applications must begin early, before the inner leaves of the plants fold in and start to form hearts. In fact, this remark applies to the treatment for either aphid or to caterpillars—they should be mastered in early stages of the attack.

The Longwood Branch forwarded specimens of potato tops that had "yellowed off" before maturity, and tubers through which grass had penetrated.

Reply—Without personal knowledge of the plants and soil, I can form no conclusion respecting the cause of the tops of these potato

plants yellowing off. The tubers submitted present a good illustration of the piercing power of a shoot when driven by the persistent pressure of growth. I have seen the same penetration exercised by the shoots from the *Oxalis cernua* (soursop), when autumn rains started them into growth in an apple orchard, where apples were piled around the tree stems. The tender leafless shoots pierced over an inch into the solid apple fruits. It is a well-known fact that the creeping stems of the couch grass of Europe (*Agropyron repens*) will damage potato tubers in this manner.

"W.S.H.," Spalding, asks for advice in starting a small orchard.

Reply—Providing the trees are sheltered, probably the best kinds to plant at Spalding would be apricots, peaches, nectarines, plums, apples, pears, quinces, figs, and almonds, as well as grape vines. The figs and apricots should be planted on the outside, on the side of the prevailing winds. Peaches, almonds, quinces, nectarines, and plums in their respective order as given, with pears and apples in the most sheltered parts. Gumtrees should be kept at least 60ft. away from the nearest row of fruit trees in a district with an annual rainfall of 18-20in. I advise cultivating the soil between the gums similarly to the tillage given between the fruit trees for the first few years, so as to encourage them to grow up quickly. In planting the rows of gums for shelter purposes the trees should be set out in equilateral triangles, like the black spaces on a draught board, instead of as squares, as this reduces the chances of the wind sweeping through wide lanes.

"W.R.S.," Arthurton, inquires the best method of curing blight in vegetables.

Reply—If by "blight" a form of aphid is meant, they may be destroyed by spraying or syringing with a decoction of tobacco juice in hot soapy water. It is always advisable to send specimens.

"G.A.," Booleroo Branch, inquires whether superphosphate is useful in the cultivation of fruit trees and vines.

Reply—Yes. Use from 1lb. to 5lbs. per tree, according to size, digging it in early in the winter in a circle just outside the spread of the branches. For grape vines use from 2ozs. to 16ozs. per plant in a similar manner.

"T.B.," Carrow, asks what is the most effective method of destroying white ants in fruit trees and woodwork.

Reply—I know of no method of destroying white ants in fruit trees, but their ravages may be checked in fences and buildings by locating the tunnels and boring holes in a downward sloping direction into the posts or timber slightly above where the termites are excavating,

and impregnating the wood with dissolved arsenic. Arsenic may be dissolved by boiling in water along with common washing soda. I suggest trying a strength made by boiling 1lb. white arsenic and 2lbs. of washing soda in 1gall. of water, and then diluting same to 5galls. Care must be exercised in preparing, keeping, and using this solution, as it is extremely poisonous to animals as well as human beings.

Reply by Mr. WALTER GILL, Conservator of Forests.

"H.R.L.," Laura, asks the cause of pepper trees shedding their leaves.

Reply—It would seem as if the trees shed their leaves owing to the great lack of moisture in the subsoil, consequent upon the unparalleled drought, which has now so fortunately broken up. I do not think the trees will die, as in the Far North during a long spell of dry weather some shrubs and trees often lose their leaves, but grow a fresh lot when favorable conditions occur.

### SUPERPHOSPHATES.

Replies by Mr. W. J. S. SPAFFORD, Superintendent Experimental Work.

"H.G.P.," Rockleigh, asks:—(1) Whether all makes of 36 per cent. to 38 per cent. water-soluble superphosphate are similar as regards plant food? (2) How many pounds of 45 per cent. to 47 per cent. superphosphate is equal to 80lbs. per acre of 36 per cent. to 38 per cent. superphosphate?

Reply—(1) This 36/38 per cent. means that the superphosphate contains from 36 per cent. to 38 per cent. of its bulk in the form of calcium phosphate soluble in water; the fertilizers are guaranteed to contain that quantity, and as plants can readily utilise plant food that is soluble in water, they must be of equal value. (2) If 100lbs. superphosphate equals 37lbs. soluble calcium phosphate, 80lbs. is equivalent to 29.6lbs. soluble calcium phosphate; and if 100lbs. equals 46lbs. soluble calcium phosphate, then 80lbs. is equivalent to 36.8lbs. soluble calcium phosphate. Therefore  $36.8 : 29.6 :: 80 : x$  equals 64.3lbs. So if the extra amount of free acid in the 45/47 per cent. superphosphate does not interfere with growth, 64lbs. of the 45/47 per cent. superphosphate is equal to 80lbs. of 36/38 per cent. superphosphate.

## Suggested Rations for Farm Horses Calculated to meet the Local Shortage of Hay and Chaff.

By ARTHUR J. PERKINS, Director of Agriculture.

There is every reason to believe that the local stocks of hay and chaff are altogether insufficient to meet the normal requirements of livestock owners through the winter and spring months of the year. Nor, unfortunately—whatever may have been thought earlier in the season—can it now be assumed that the local deficiency in coarse fodders can be made good from outside sources. The Grain and Fodder Board, acting under Government instructions, have, it is true, made extensive purchases of hay and chaff in the other States. Unfortunately much of this produce has not yet been delivered; and the Governments of both Victoria and New South Wales appear determined to prevent us from securing what is still within their territories. Further, the chances of securing good hay from either New Zealand, or North or South America are practically nil. New Zealand, apparently, is, like ourselves, feeling the pinch of the drought, and has nothing to spare. And whilst both wheaten and oaten hay have been offered us tentatively from California, the offers have never definitely materialised in a form that we could accept. Indeed there are good reasons for believing that wheaten hay is unobtainable at any time outside of Australasia; and when it is offered from distant outside sources, in times of emergency, there is reason to suspect that on closer inspection it is not likely to be distinguishable from straw. Oaten hay is more generally availed of in other countries, and is less open to suspicion; unfortunately even this type of hay is not likely to become available in exportable quantities until next hay harvest in the Northern Hemisphere, i.e., not earlier than July at ports of shipment, and altogether too late for our own purposes.

It is fairly clear, therefore, that we are thrown back on our own resources; and since in the matter of coarse fodders they are very limited, it is essential that we husband them with the utmost care. It is customary in this country, particularly on farms, to feed horses on wheaten hay chaff, to the almost total exclusion of the concentrates in common use in other countries. It is open to question whether this practice is altogether commendable even in normal seasons; but it is manifestly suicidal in present times of shortage and high prices.

The position we have to face is this:—unless we take early steps to replace some of the chaff that is being fed to livestock by equivalent quantities of concentrates, we shall very shortly find ourselves compelled to feed our livestock, if we wish to save them, on concentrates alone. And this is neither a natural nor an economical feeding practice.

No doubt many livestock owners know from experience in what proportions these concentrates can be fed to their livestock; on the other hand, there are many who lack such experience; and for the guidance of the latter I have summarised below in as many combinations as possible the various foodstuffs that are available for us in the form of rations respectively for heavy horses (1,500lbs. or thereabouts) and for light horses (1,000lbs. or thereabouts).

These rations are for horses doing ordinary farm work, and are based on the following facts. I have assumed, on data known to me, that a heavy draught, doing ordinary farm work, will consume 56lbs. of good wheaten chaff in a day; and a light horse about 38lbs. From a dietary point of view, this is very far from being a satisfactory ration; it is far too bulky in character, leads to the distention of the abdomen, and is not sufficiently rich in protein to make good normal body waste of tissue. The rations indicated below, whilst being all of better feeding value, are in other respects equivalent to 56lbs. and 38lbs. of good wheaten chaff respectively; and at the present moment they present the additional advantage of being cheaper than simple wheat chaff rations.

TABLE OF ALTERNATIVE DAILY RATIONS FOR HORSES DOING ORDINARY FARM WORK AND WHOLLY STABLED.

| Ration. | Constituents in Ration. | Heavy Horses (1,500lbs.). |                         | Light Horses (1,000lbs.). |                         |

|         | Lucerne hay .....       | 12                        | —                       | 8                         | —                       |
|         | Barley .....            | 15                        | 3 11½                   | 10                        | 2 8                     |
| XII.    | Good cereal straw ..... | 20                        | —                       | 14                        | —                       |
|         | Molasses .....          | 3                         | —                       | 2                         | —                       |
|         | Barley .....            | 12                        | —                       | 8                         | —                       |
|         | Bran .....              | 12                        | 3 11½                   | 8                         | 2 8                     |

In these tables the value of the ration has in all cases been calculated on the following current prices :—

|                         |                    |
|-------------------------|--------------------|
| Wheaten hay chaff ..... | £12 per ton        |
| Cereal straw .....      | £6 per ton         |
| Lucerne hay .....       | £8 10s. per ton    |
| Molasses.....           | £5 15s. per ton    |
| Barley .....            | 6s. per bushel     |
| Oats .....              | 5s. 9d. per bushel |
| Bran .....              | 2s. 2d. per bushel |

Very naturally the values of the various rations will tend to fluctuate with the prices for foodstuffs current over the next few months. It may be stated here that the Government are expecting several important cargoes of oats, barley, and bran, all of which have been acquired at considerably lower c.i.f. prices than those indicated above; and they may be looked forward to as tending to cheapen considerably the present cost of upkeep of horseflesh.

It may be repeated that in these tables each one of the rations given corresponds to a daily supply of 56lbs. or 38lbs. of good wheaten hay chaff. Hence, if personal experience tends to show

that a less quantity of wheaten chaff meets the requirements of individual cases, the rations may be reduced accordingly, providing that the reduction is made proportional for each one of the constituents indicated.

For those who have no experience of grain feeding, it should be stated that it is as a rule preferable to crush slightly hard grain, such as barley. This is particularly necessary in the case of old horses, whose teeth generally are more or less out of order. If the grain cannot conveniently be crushed on the farm, soaking in warm water over night may be recommended. Molasses should be diluted with warm water and mixed with the coarse fodders immediately before feeding.

The daily rations indicated above have been worked out for horses that are being fed exclusively in the stable; it goes without saying that if, as is frequently the case, horses are turned out at night over passable pasture, the rations may be reduced in proportion to the value of the pasture. At the same time it should be borne in mind that a hungry horse that has to walk about all night in search of food cannot be expected to do the same amount of work the next day as a horse that is well fed and snugly stabled.

Finally, by way of caution to the inexperienced, it should be stated that very few animals are able to take up suddenly and without inconvenience a new form of diet. Horses hitherto fed exclusively on wheaten chaff should not be given suddenly a full grain ration. If the change is led up to gradually ill effects will generally be avoided.

#### “TAKE-ALL.”

This is the popular name of a fungus disease which does considerable damage to the wheat crops in this State. The disease is always present, but unless it receives a check in its young stages, the wheat plant is, as a rule, able to withstand the ravages of the pest. The main causes of checks to the young growth are found in the condition of the soil, so it behoves the farmer to see that as nearly as possible an ideal seed bed is prepared. To attain this end the aim should be to have the immediate surface fine and loose, with the soil well compacted below. Care should be taken to avoid the creation of air spaces in the under soil, as these always mean a temporary check to any wheat plant if the roots reach them. Rolling overcomes this condition. Oats are not liable to attack to any extent, and are therefore useful as an aid to starving out the fungus when used as a rotation crop on badly affected land.

## Suggested Rations for Dairy Cattle Calculated to Meet the Local Shortage of Ordinary Foodstuffs.

By ARTHUR J. PERKINS, Director of Agriculture.

In an earlier report I had occasion to draw up a list of suggested rations for working horses calculated to meet the local shortage of coarse fodders. It has been suggested to me that a similar list might with advantage be drawn up for dairy cattle. I am bound to state, however, that the task is more complicated than was the case for working horses. It is customary, for example, to allow dairy cattle to graze far more freely than working horses; and undoubtedly the grass they consume in this fashion must be deducted from any stable ration that would in its default be fed them. Nor, in this direction, is it easy to calculate the value of what grazing may be available; indeed, in exceptional circumstances, the pasture may be of such quality as to render stall feeding altogether unnecessary. These are contingencies, however, which have little or no bearing on our present position; the magnificent rains that have recently been vouchsafed us have no doubt relieved the general agricultural condition very considerably; very shortly, too, they will provide, in many districts, good feed for lambing flocks; unfortunately, in the great majority of cases, the same cannot be said of the kind of pasture essential to the upkeep of a good flow of milk. Unless, indeed, we have before us an exceedingly mild winter, it seems probable that good dairy pasture will not be available until August and September. In the circumstances, if the flow of milk is to be maintained, cows will have to be fed regularly and heavily; and the rations indicated below are suggested in the belief that little or no suitable grazing will be available for milch cows for some time to come.

Another difficulty connected with dairy cattle rations is that not only the size of the animal has to be taken into consideration, but additionally the quantities of milk individual cows are supplying. Accordingly, in the suggested rations indicated below the requirements of both a 1,000lb. cow (average crossbred) and a 750lb. cow (Jersey) are given, with daily supplies of 40lbs., 30lbs., 20lbs., and 10lbs. of milk respectively.

Where horses were concerned, I was able to take a simple wheaten hay chaff ration as a standard of comparison; for dairy cattle this

is not possible, since hay chaff alone does not form a suitable ration for the purpose. I have, therefore, taken as a standard a mixture of wheaten chaff and bran as indicated in Ration 1.

|                      | Value at present prices ..... | 2 5                | 1 10¼   | 1 6     | 1 0½    |
| VII.                 | Green lucerne .....           | lbs. 22            | lbs. 22 | lbs. 16 | lbs. 10 |
|                      | Bran .....                    | 14                 | 11      | 7       | 3       |
|                      | Barley (crushed) .....        | 4                  | 4       | 5       | 5       |
|                      |                               | s. d.              | s. d.   | s. d.   | s. d.   |
|                      | Value at present prices ..... | 2 4¾               | 2 0¾    | 1 7¾    | 1 1½    |
| VIII.                | Egyptian clover.....          | lbs. 22            | lbs. 22 | lbs. 16 | lbs. 12 |
|                      | Bran .....                    | 15                 | 11      | 7       | 4       |
|                      | Barley (crushed) .....        | 4                  | 4       | 5       | 5       |
|                      |                               | s. d.              | s. d.   | s. d.   | s. d.   |
|                      | Value at present prices ..... | 2 6                | 2 0¾    | 1 7¾    | 1 3     |

These suggested rations, which have been prepared in collaboration with the Dairy Expert, have no claim to being ideal ones; the suggestions merely represent an attempt to utilise in the best possible

manner what available foodstuffs we have at the present moment and are likely to have for the next three months. The values have been calculated on the following basis:—

|                       |                    |
|-----------------------|--------------------|
| Wheat chaff .....     | £12 per ton        |
| Lucerne hay .....     | £8 10s. per ton    |
| Cereal straw .....    | £6 per ton         |
| Cocoanut cake .....   | £10 10s. per ton   |
| Molasses .....        | £5 15s. per ton    |
| Barley .....          | 6s. per bushel     |
| Oats .....            | 5s. 9d. per bushel |
| Bran .....            | 2s. 2d. per bushel |
| Green barley .....    | £1 per ton         |
| Green lucerne .....   | £2 per ton         |
| Egyptian clover ..... | £2 per ton         |

These prices, no doubt, will vary somewhat over the next three months; it will be satisfactory to all to realise, however, that the Government purchases from abroad of barley, oats, bran, &c., will soon have the effect of bringing down very considerably the cost of concentrates.

It should be stated that for cows of the same weight and milk yields all the rations suggested have equal food values. In terms of wheaten chaff they may be said to correspond to the following values for 1,000lbs. cows:—49lbs. of wheaten chaff, of a present value of 5s. 3d., for cows yielding 40lbs. of milk; 41lbs. of wheaten chaff, of a present value of 4s. 4½d., for cows yielding 30lbs. of milk; 34lbs. of wheaten chaff, of a present value of 3s. 7½d., for cows yielding 20lbs. of milk; and 26lbs. of wheaten chaff, of a present value of 2s. 9½d., for cows yielding 10lbs. of milk. It is not suggested for a moment that these quantities of wheaten chaff are suitable for cows in milk; but merely that, as food values, they correspond approximately to the rations indicated in the table.

Mr. Suter wishes to emphasize the fact that at this time of the year warmth and shelter are not only essential to the wellbeing of cows and the production of milk, but that they lead to a notable economy in the matter of food. If cattle are exposed to low temperature and rough weather they must eat more to maintain their normal body temperature; and if additional food is not supplied, material which should under more favorable conditions be used in the manufacture of milk will be burnt up in the body very much in the same way as fuel in a grate. Hence Mr. Suter strongly urges the judicious use of rugs if cows are turned out in the open, and general accessibility to shelter such as would be offered by sheds, trees, hedges, &c.

Finally, in a second table have been worked out suitable maintenance rations for dry cows. These rations are calculated to keep the animals from going back until grazing becomes available, providing always that they have access to suitable shelter.

TABLE OF ALTERNATIVE DAILY MAINTENANCE RATIONS FOR DRY COWS, NOT HAVING ACCESS TO PASTURE BUT SUITABLY SHELTERED FROM ROUGH WEATHER.

| Ration. | Constituents in Ration. | 1,000lb. Cow. |        | 750lb. Cow. |        |
|---------|-------------------------|---------------|--------|-------------|--------|
|         |                         | Quantities.   | Value. | Quantities. | Value. |
|         |                         | lbs.          | s. d.  | lbs.        | s. d.  |
| I.      | Wheaten hay chaff ..... | 17            | —      | 13          | —      |
|         | Bran .....              | 2             | 2 0½   | 1½          | 1 6½   |
| II.     | Good cereal straw ..... | 16            | —      | 12          | —      |
|         | Lucerne hay .....       | 2             | —      | 1½          | —      |
|         | Barley (crushed) .....  | 5             | 1 7½   | 4           | 1 3    |
| III.    | Good cereal straw ..... | 20            | —      | 15          | —      |
|         | Oats .....              | 6             | 1 11½  | 4½          | 1 5½   |
| IV.     | Good cereal straw ..... | 23            | —      | 17          | —      |
|         | Molasses .....          | 2             | —      | 1½          | —      |
|         | Coconut cake .....      | 3             | 1 7½   | 2           | 1 2    |
| V.      | Good cereal straw ..... | 13            | —      | 10          | —      |
|         | Bran .....              | 2             | —      | 1½          | —      |
|         | Barley (crushed) .....  | 5             | 1 6½   | 3½          | 1 1½   |
| VI.     | Green lucerne .....     | 12            | —      | 9           | —      |
|         | Barley .....            | 7             | 1 0½   | 5           | 0 9    |
| VII.    | Green barley .....      | 18            | —      | 14          | —      |
|         | Barley (crushed) .....  | 6             | 0 10½  | 4½          | 0 8    |
| VIII.   | Egyptian clover .....   | 17            | —      | 13          | —      |
|         | Barley (crushed) .....  | 6             | 1 0½   | 4½          | 0 9½   |

The maintenance rations in the above table correspond in food values in each case approximately to 20lbs. of wheaten chaff, of a present value of 2s. 1½d., for 1,000lb. cows, and to 15lbs. of wheaten chaff, of a present value of 1s. 7½d., for 750lb. cows.

The chief timber-producing countries of the world have the following percentage of territory under forest:—Sweden, 52.2; Russia, 43; Germany, 25.9; Austria-Hungary, 29.6; France, 15.6; United States, 33.6; Canada, 22.3. Australia has the smallest area of timber forest in proportion to her total land surface. Some statistics give the forest area at over 100,000,000 acres, or about 5 per cent.; but the Victorian Conservator of Forests (Mr. H. R. Mackay) believes that estimate to be excessive. He puts down the true forest area as less than 4 per cent. of the total land area.

## CRESS OR SPURIOUS BUCKBUSH.

By F. E. PLACE, B.V.Sc., M.R.C.V.S., Veterinary Lecturer.

For the last five years the writer has from time to time received complaints that the plant known as cress or buckbush in the desert mallee country and similar Murray country has been responsible for deaths of horses, while an equal or greater number of correspondents have asserted that it is a real good feed and a great stand-by in times of drought.

On account of this divergence of opinion, careful watch has been kept on the plant, and the following notes regarding it may be of use:—The plant has been identified as *Gyrostemon cyclotheca*, order *Phytolaccaceae*. Nowhere in available literature are there any accounts of its poisonous qualities. This is probably because, being an inhabitant of South-West Australia, it has failed to come under the observation of toxicologists.

Other members of the family, such as *Phytolacca decandra*, are well known in medicine as having potent qualities. The one just mentioned is commonly known in America as American nightshade, or pokeweed, and its uses are various. The green shoots and berries are admittedly poisonous, when raw, but are used as spinach and for coloring wine when boiled. In medicine, the plant is used with success in mammitis (udder ill), and is supposed to give relief in cancer of the breast and some syphilitic conditions. The poisonous action of the plants of this family are that they produce vomiting, pain in the belly, diarrhoea, shortness of breath, suffocation, and paralysis of the lungs and heart. The parts of the plant found to be most virulent are the young shoots, roots, and fruit.

The facts in the last two paragraphs form an interesting commentary on a letter recently received from a close observer (Mr. A. H. Wilkins, of Lamerob), which so well describes the conditions noted by the writer that extracts will be freely quoted from it. He says:—"On Sunday afternoon last the horses were apparently all well. Monday morning two out of nine were dead, both of the same complaint. It is easily identified by the foam blown from the nostrils. The rest seemed all right till Wednesday, when another died. On Thursday another developed the cough and slight running from the nostrils, but the symptoms cleared off during the night, and

the horse seemed quite well in the morning. I am sending the bush to know if it is really a poison weed. Personally I saw no symptoms whatever of the beast being poisoned. There were none of the twitchings and stiffness of the legs I have seen with poisoned stock. The horse died on Wednesday with its front legs bent back. It seemed to be lung trouble. The horse showed no other sign of pain whatever. The horses that died have only been out on this country for 17 days. Two were three years old and one two years old. One was in good condition, the other two fair. Personally I have had horses on the country since September 27th (more than six months). They are aged from 1 year to 10 years, and are all in the pink of condition. Their coats shine as though stable fed. They run over the same country where the deaths have occurred, and eat the same bush, which has berries on about 5 per cent. of the plants now. The bush grows in patches here and there—not in thick clumps. The horses all water at the same soak, and so far, out of 40 brought here in September, none have died of this complaint. It seems to be among the new arrivals, or horses that have been here a fortnight or three weeks.”

The correspondent adds a description of symptoms:—“The horse that died in the desert south of Lameroo was two years old. At 8.30 a.m. it was feeding with other horses on country that had been burnt 15 months previously. From 8.30 to 8.50 the horse was driven very slowly with others to water. At 8.50 it started to cough every minute or so (a short cough); at 9 a.m. the cough was more severe, water and bubbles coming from both nostrils; breathing becoming more labored till 9.15, when cough ceased, but there was more nasal discharge. During this 25 minutes the horse passed dung on eight occasions, at first normal—in this country the dung is in colour and appearance like that of horses fed on hay chaff cut fairly ripe. The dung got loose and sloppy between 9.15 and 9.50, and the breathing was labored, sounding like that of a person with a bad attack of bronchitis. At 9.50 the horse went down, but got up again immediately. Breathing was almost impossible when down. On getting up the fluid gushed from both nostrils. From 9.50 to 10.20 the discharge was less, and the horse walked 300yds. or so to the other horses. From 10.20 to 10.35 the discharge from the nostrils increased, with frequent gushing and much froth. The discharge and labored breathing increased in severity till 10.50, when the horse threw up his head, took a few steps backwards, rolled on its side, lifted its head once or twice, and died. During the whole

two hours there was no sign of pain except the breath, and for the last five minutes its actions resembled those of a horse gradually being choked."

The *post mortem* was described by the same observer:—"Bowels in very healthy condition, hinder bowel empty, as might be expected after 11 passages of dung in quick succession. Liver and spleen healthy. The chest contained two or three pints of brandy-colored fluid, which had a very sour smell. The lungs were much inflamed, dark-red inside, very hard to the touch, instead of the usual spongy feeling. There was about 1 pint to 2 pints of similar fluid in the heart bag, and at the bottom the fluid had congealed to a jelly, but did not touch the heart. There was no sand in the bowels, and only a few worms about 1½ in. long."

Little comment is needed on this lucid description, except to say that to the layman a horse suffering from very severe chest trouble does not appear to be in pain. The fact that the country had been burnt points to the bush growth being succulent, and most of the complaints come in when winter feed is springing. The impossibility of breathing when down was, of course, due to the anatomical arrangement of the horse's respiratory organs demanding a standing posture when they are diseased. The final suffocation is quite symptomatic of the action of this family of plants, as observed in U.S.A. The observer's description of the lung trouble would, however, seem to imply congestion rather than inflammation, and the writer's observations favor this condition rather than an inflammatory one. The difference is not easily made out by the layman.

A point of great importance is the one noticed, namely, that newcomers are the ones to succumb most readily, while those that have been eating the plant regularly apparently do so with impunity, although every now and then a complaint reaches the writer of a horse dying that has been on the bush for a long time. In such cases it invariably appears that quick or hard work is undertaken immediately before death, which is compatible with both the paralytic action of the poison, as well as with distention of the stomach, and mechanical interference with breathing, resulting from its acrid action upon the stomach.

It may fairly be deduced that the plant has a specific paralysing effect upon the respiratory and cardiac nerves, and acrid chologogic action of less virulence; and that young, inexperienced, and greedy feeders taking shoots, roots, or berries are likely to succumb, especially when new to the plant, while older animals, picking and

choosing, do not as a rule get a lethal dose, though they, too, may succumb when conditions are unfavorable, such as coming on to the plant with an empty stomach, or doing fast and hard work with a large quantity of it in that organ. These facts suggest easy means of prevention, and probably, if time allowed, treatment of an affected beast would point to light bleeding to relieve the congestion, and the administration of milk to counteract the chemical properties of the poison. The proverb says "One man's meat is another man's poison," a saw which may well be applied to cress or spurious buck-bush.

### FRUIT SALES IN LONDON.

The following is an extract from the Trade Commissioner's report, dated London, April 9th, 1915 :—

#### DRIED FRUIT.

*Currants*.—Business, on the whole, has been very satisfactory, considering the limited selection offering. Quotations are—Pyrgos, 24s. 3d. to 24s. 6d. ; Amalias, 25s. 6d. to 26s. ; Gulf and Patras, 26s. 6d. to 30s. ; Zante, 25s. 6d. to 29s. ; Vestizza, 28s. to 34s.

#### Statistics to March 31st.—

|                                                                  | 1915.  | 1914.     |
|------------------------------------------------------------------|--------|-----------|
|                                                                  | Tons.  | Tons.     |
| Total arrivals from commencement of season to March 31st .....   | 26,577 | .. 24,911 |
| Total clearances from commencement of season to March 31st ..... | 22,292 | .. 19,786 |
| Estimated stock in bond on March 31st                            | 2,659  | .. 5,009  |

*Raisins*.—The little business passing has been in half boxes, at 36s. to 40s. ; and quarter boxes, at 40s. to 42s. The arrivals to March 31st, including transit fruit, amounted to 2,954 tons, as compared with 3,883 for the corresponding period last year, or a decrease of 929 tons.

*Sultanas*.—The arrival of the *Bulgarian* and *Roma* with 45,000 boxes from neutral ports helped to replenish the very meagre stocks in first hands. The trade has been fairly active, with sales taking place daily ; but prices have receded, mostly through a desire on the part of holders to clear their small stocks up. Sales are—Common, 49s. to 50s. ; ordinary to fair, 51s. to 53s. ; good, 54s. to 55s. ; fine, 56s. to 58s. ; Greeks, 55s. to 60s. The arrivals of Smyrna to March 31st, including transit fruit, were 468,566 packages, or a decrease of 258,500 packages on the figures for the corresponding period in the previous year.

*Figs*.—Bags of naturals from America have changed hands at 25s. ; other sales are at 26s. to 30s.

## BLACK JAPANESE MILLET ON THE RECLAIMED MURRAY SWAMPS.

By ARTHUR J. PERKINS, Director of Agriculture.

The disastrous character of the 1914-15 season, from the point of view of the growth of our usual livestock foodstuffs, is not likely to be forgotten for many years. Amongst the various expedients set going to meet the very abnormal conditions with which we were faced must be mentioned the efforts put forth to utilise to their utmost the unallotted areas of recently reclaimed Murray swamp lands. The Director of Irrigation endeavored to raise on these lands those forage crops which appeared likely to yield the most profitable returns. Among the crops tested for the purpose was what is known as Black Japanese Millet, apparently an improved rank-growing variety of *Panicum Crusgalli*; and it is to this particular crop that these notes make reference.

This millet was sown, apparently, on land not as yet completely reclaimed—at all events, not to the extent of the complete removal of injurious saline matter. Indeed, according to Mr. McIntosh, winter crops of barley and oats, which had preceded the millet on the same land, failed almost entirely as a result of the action of the rising salt.

There is good evidence to show that as a standing crop the Japanese millet presented a very fine appearance. Eventually it was cut for hay and chaffed. The average yield, calculated on the hay-dry chaff, did not come up to expectations; it did not exceed  $2\frac{1}{2}$  tons to 3 tons to the acre, whilst fully 4 tons were anticipated. It is possible that these rather disappointing yields are to be attributed to irregular growth over certain portions of the areas sown; and possibly, too, to a certain amount of wastage as between the binder and the chaffcutter.

In our experience, millet chaff was a new type of livestock foodstuff, and it was thought advisable to submit it to various tests whilst the opportunity presented itself. At the request of the Director of Irrigation, I had forwarded to the Principal of the Agricultural College samples of the chaff for chemical analysis, and for palatability tests by livestock, to which it would come as a foreign foodstuff.

## PALATABILITY OF BLACK JAPANESE MILLET HAY.

In the matter of palatability, the Principal (Mr. W. J. Colebatch, B.Sc., M.R.C.V.S.) reported as follows:—"The amount of millet available for palatability trials was insufficient for a wholly satisfactory experiment. A certain period, say, a week at least, should be allowed for the 'strangeness' to wear off, even in the case of two such greedy feeders as 'Clown' and 'Inch' (the two horses tested), but I think it is clear that horses will take to it well enough; and there are indications also that the ripe fodder is preferred to that cut in an immature stage of growth."

It should be stated that samples of millet hay chaff, cut in three different stages of growth, were sent to Roseworthy for testing. Samples were described as follows by the Irrigation Department:—Sample No. 1—Cut when the ear was showing in the shot blade. Sample No. 2—Cut when just coming into ear. Sample No. 3—Cut when in full ear. It will be noted that according to Mr. Colebatch the ripest chaff was preferred by the Roseworthy horses.

## GENERAL ANALYSIS OF MILLET HAY.

The analysis of the millet chaff was carried out by the State Agricultural Chemist (Mr. J. H. Phillips, B.Sc.). His results are indicated below in Table I., in which the analyses of millet hay, cut in the three stages of development indicated above, are shown side by side with the analysis of wheaten hay, cut 20 days after the full bloom, and representing good standard hay.

TABLE I.—*Showing Analysis of Black Japanese Millet Hay cut in three different stages of development comparatively with that of good standard Wheaten Hay. All results expressed in terms of oven-dried material.*

|                      | Black Japanese Millet.                   |                                 |                        | Standard<br>Wheaten<br>Hay. |

| Proteins .....       | 13.83                                    | 9.19                            | 10.50                  | 5.69                        |
| Fat .....            | 1.05                                     | 0.77                            | 0.72                   | 0.86                        |
| Carbo-hydrates ..... | 35.62                                    | 38.14                           | 38.37                  | 59.45                       |
| Fibre .....          | 30.26                                    | 35.22                           | 33.68                  | 27.10                       |

## MOISTURE CONTENTS OF MILLET HAY.

From Table I. we gather, in the first place, that the millet hay, as might be expected from its coarse texture, retains on drying about one-half more moisture than is the case with average wheaten hay.

Hence, if we assume the average moisture contents of South Australian wheaten hay to be 10 per cent.—and this assumption is justified in practice—the moisture contents of millet hay would be about 15 per cent. This point is not without its importance, since other things being equal, the value of any foodstuff is proportional to the dry matter it represents; and in this connection high moisture contents naturally implies corresponding reduction in available dry matter. On the moisture proportions indicated above, and other things being equal, 1 ton of millet chaff would be the feeding equivalent of 18cwt. 100lbs. of normal wheaten chaff.

#### MINERAL CONTENTS OF MILLET HAY.

Another very striking feature brought out in Table I. is the abnormally high mineral contents of the millet hay. In the earlier cut sample of this hay nearly one-fifth of the dry matter was mineral in character; and in the later cuts the proportion was still in excess of 16 per cent. Proportions of minerals of this order are extraordinarily high, and will certainly account in no small degree for the distaste shown for this hay, particularly in the immature stage, by livestock to which it was fed. The proportions for all cuts alike stand in strong contrast to the 6.9 per cent. of mineral matter in normal wheaten hay.

On noting these abnormal mineral percentages in the millet hay, Mr. Colebatch rightly conceived that the matter called for further investigation; and he accordingly asked the State Agricultural Chemist to make a special analysis of the ash, with a view to ascertaining its peculiarities. Mr. Phillips thereupon determined in the three samples of ash the proportions of silica and chlorine, and made a more or less complete analysis of the ash of sample No. 1 (the earliest of the cuts). Data available for the three samples are indicated below in Table II.

TABLE II.—*Showing Silica and Chlorine present in Ash of Japanese Millet Hay cut in three different stages of growth.*

| Samples.    | Silica and Insoluble Matter. | Chlorine. | Equivalent Sodium Chloride (Common Salt). |
|-------------|------------------------------|-----------|-------------------------------------------|
|             | %                            | %         | %                                         |
| No. 1 ..... | 35.80                        | 14.7      | 24.25                                     |
| No. 2 ..... | 35.79                        | 14.5      | 23.92                                     |
| No. 3 ..... | 38.18                        | 12.7      | 20.97                                     |

We shall content ourselves with noting for the present that whilst with advancing maturity there appears to be in the millet hay an increase in the proportion of silica present, there is a decrease in that of chlorine. It should be observed, too, that whilst the increase in silica characteristic of advancing maturity is both

proportional and absolute, there is no reason for supposing that the proportional decrease in chlorine in any way implies an absolute decrease in the amount of this substance absorbed by the plants in the course of their growth.

Data concerning the complete analysis of the ash of the earliest cut of millet hay are indicated below in Table III., comparatively with a similar analysis for ripe wheat.

TABLE III.—*Showing Analysis of the Ash, or Mineral Matter, of Millet Hay comparatively with that of ripe Wheat.*

| Constituents.                       | Early-Cut<br>Millet Hay. | Ripe<br>Wheat. |
|-------------------------------------|--------------------------|----------------|
|                                     | %                        | %              |
| Total ash in dry matter .....       | 19.24                    | 5.59           |
| Silica and insoluble matter .....   | 35.80                    | 59.20          |
| Iron, alumina, and phosphates ..... | 3.40                     | 9.65           |
| Lime .....                          | 2.90                     | 4.23           |
| Magnesia .....                      | 4.25                     | 2.58           |
| Potash .....                        | 11.06                    | 16.01          |
| Sulphuric anhydrid .....            | 9.09                     | 3.56           |
| Chlorine .....                      | 14.70                    | 1.60           |
| Soda and undetermined .....         | 18.80                    | 3.17           |

It is regrettable, of course, that for the purposes of the present comparison, the analysis of the ash of wheaten hay, that is to say of wheat in a state of development more nearly approaching that of the millet hay under consideration, is not at present available to us. In the circumstances I have had to make use of an analysis concerning fully ripened wheat.

We may observe, in the first place, that the proportion of mineral matter in the dry matter of the millet hay is almost four times that indicated for ripe wheat. Undoubtedly the immaturity of the millet would account for some slight increase above that noted for ripe wheat. We may see, for instance, in Table I., that the mineral matter in standard wheaten hay is represented by 6.9 per cent., which is, however, still two-thirds lower than the figure indicated for millet hay. Abnormally excessive presence of total minerals may, therefore, be admitted.

Coming to details, we see, in the first place, that there is less silica in the millet hay than in the ripe wheat; this may represent a characteristic difference between the two plants, or more probably is to be attributed to the immaturity of the millet, since silicates appear to accumulate as maturity advances.

The most striking feature in the analysis, however, is the abnormally high proportion of chlorine, soda, magnesia, and sulphates in the ash of the millet hay. We know that this hay has been grown on recently reclaimed land, as yet more or less impregnated with injurious saline matter, and we must infer that the abnormally

mineral character of the dry matter of the hay is due to the absorption by the millet of sodium and magnesium chlorides, and sulphates of soda and magnesium, all of which, when present in excess in the soil, are injurious to normal vegetation.

It has already been stated that winter crops of oats and barley failed on the same land which eventually carried a fine summer crop of millet. It is clear, therefore, that not only will Japanese millet grow vigorously on more or less salt-impregnated land, but additionally by absorbing into its own tissues, without apparent hurt to itself, injurious saline matter, it will, by sweetening the soil, help to prepare the way for more delicate crops.

That the quantities of saline matter removed by the crops under consideration are by no means inconsiderable may be judged by the following facts. We know that the average yield was represented by about 3 tons of hay-dry material to the acre. If we assume the saline matter absorbed by the crop to have been originally in the form of sodium chloride and sulphate of sodium and magnesium respectively, the quantities of injurious salts removed from the soil by the crop would be represented by about 400lbs. to the acre. At this rate of sweetening, a few crops of millet would soon re-establish soils more or less unsuited to other forms of cropping.

#### ORGANIC CONSTITUENTS OF MILLET HAY.

A further reference to Table I. will show that whilst the proteins in the dry matter of millet hay are thrice as abundant as is the case in wheaten hay, the carbohydrates are considerably less; and the more or less indigestible fibre appreciably higher. Now, it is customary to look with favor upon foodstuffs the protein contents of which are high; and from this point of view the millet hay certainly appears satisfactory. In a general estimate of its value, however, there are other factors to be taken into consideration, with which we shall now proceed to deal. In the first place, however similar in type they may be, it is impossible to compare two foodstuffs on the mere analysis of their dry matter, as indicated in Table I.; it is essential that the proportion of useful constituents be calculated in relation to the moisture contents of the foodstuffs. There is also to be taken into account their relative digestibility. It is true that we have no exact figures upon which the digestibility of the constituents in millet hay can be accurately based. In 1912, however, I had occasion to determine at Roseworthy the digestibility of wheaten hay in various stages of development (*vide* "Further Investigations into Factors affecting the Handling of Wheaten Hay, including a Study of Digestibility"); and in the present instance

I propose assuming that the digestibility of the constituents in the millet hay will be in the same ratio as that of those of the standard wheaten hay, viz.:—Proteins, 53.87 per cent.; carbohydrates, 62.91 per cent.; fat, 62.91 per cent.; fibre, 32.42 per cent. And it is upon the above basis that data indicated below have been calculated.

TABLE IV.—*Showing Organic Constituents in Millet and Wheaten Hay calculated on a 15 per cent. and 10 per cent. moisture content respectively, together with actual Digestibility in case of Wheaten Hay, and assumed Digestibility in case of Millet Hay.*

|                      | Millet Hay. |                     | Wheaten Hay. |                     |
|----------------------|-------------|---------------------|--------------|---------------------|
|                      | Total.<br>% | Digestibility.<br>% | Total.<br>%  | Digestibility.<br>% |
| Moisture .....       | 15.00       | —                   | 10.00        | —                   |
| Proteins .....       | 9.92        | 4.81                | 5.12         | 2.76                |
| Fat .....            | 0.61        | 0.38                | 0.77         | 0.48                |
| Carbo-hydrates ..... | 32.92       | 20.71               | 53.50        | 33.66               |
| Fibre .....          | 28.63       | 9.28                | 24.39        | 7.91                |

On the data indicated in Table IV. it is possible to establish a rough comparison of the feeding value of these two hays. This comparison is based on the available "energy" or "fuel value" of the digestible material in the hays. In comparisons of this kind the relative fuel value of fat is given as 9, that of proteins as 5, and that of carbohydrates and fibre as 4. On this basis we have the following relative results:—

TABLE V.—*Showing Relative "Fuel Value" of Digestible Material in Millet and Wheaten Hay respectively.*

| Constituents.                   | Digestible Material. |              | Relative Food Values. |              |
|---------------------------------|----------------------|--------------|-----------------------|--------------|
|                                 | Millet Hay.          | Wheaten Hay. | Millet Hay.           | Wheaten Hay. |
| Proteins .....                  | 4.81                 | 2.76         | 24.05                 | 13.80        |
| Fat .....                       | 0.38                 | 0.48         | 3.42                  | 4.32         |
| Carbo-hydrates .....            | 20.17                | 33.66        | 82.84                 | 134.64       |
| Fibre .....                     | 9.28                 | 7.91         | 37.12                 | 31.64        |
| Total relative fuel value ..... |                      |              | 147.43                | 184.40       |

On this rough comparison, therefore, the feeding value of these two hays is in the proportion of 147 : 184, i.e., one ton of prime wheaten hay will go as far as  $1\frac{1}{4}$  tons of the millet hay under consideration, on the understanding that we have assumed both hays to be to an equal degree digestible. It should be added that this evident inferiority of the millet hay that we have been considering would certainly be less pronounced in the case of millet hay less heavily charged with saline matter.

## STARCH EQUIVALENTS.

It has become customary within recent years to compare foodstuffs on the basis of what is known as their "starch equivalence," i.e., the proportion they are supposed to bear to 100lbs. of pure starch in the production of energy or in the manufacture of body fat. In determining the "starch equivalence" of any foodstuff allowance is always made for the energy absorbed in the work of mastication and digestion—a figure which varies considerably according as the foodstuff is concentrated, as in the case of grain or cake, or is coarse and bulky, as in the case of hay or straw. This method of appreciating the value of a foodstuff presents, therefore, the advantage of rendering possible the comparison, *inter se*, of two or more foodstuffs differing essentially in character, such as, for example, crushed oats on the one hand, and wheaten hay on the other.

In the matter that at present concerns us it is quite possible to compare together on the lines of starch equivalence the millet hay grown on the Murray Swamps and standard wheaten hay. We have again to assume, however, that the digestibility of the various constituents in the millet hay is the same as that experimentally determined for standard wheaten hay. On these premises we find the starch equivalent of the millet hay to be represented by 18.09 per cent., i.e., 100lbs. of this hay has a feeding value equivalent to 18.09lbs. of pure starch; whilst the starch equivalent of standard wheaten hay is 30.93 per cent., i.e., 100lbs. of wheaten hay has a feeding value equivalent to 30.93lbs. of pure starch.

In this comparison the millet hay comes out even worse than in a comparison of respective fuel values. On these grounds 1 ton of standard wheaten hay may be said to go as far as 1 ton 14cwts. of Japanese millet hay.

## ALBUMENOID RATIO.

The albumenoid ratio of a foodstuff is the relation found to exist between the non-nitrogenous digestible organic matter of the foodstuff and its digestible proteins. This relation is said to be "narrow" or "wide," according as the proportion of the digestible protein is more or less great. Generally speaking, foodstuffs with narrow albumenoid ratios are considered richer and better adapted to young growing animals, and those developing high muscular power. In this connection ratios of 1 : 3 and 1 : 5 would be considered narrow ratios; whilst 1 : 10 and over would be considered wide.

From this particular aspect the millet hay compares very favorably with the wheaten hay, owing to the high proportion of proteins present. The albumenoid ratio of the millet hay (assuming it to be of a digestibility equal to that of wheaten hay) would be represented by 1 :  $6\frac{1}{2}$ , a ratio favorable to horses doing ordinary work; whilst that of wheaten hay is 1 :  $15\frac{1}{2}$ , a ratio which in the rations of working horses calls for the addition of some more highly nitrogenous foodstuff.

#### IMPORTS AND EXPORTS OF PLANTS, FRUITS, ETC.

During the month of March, 1915, 14,467bush. of fresh fruit, 7,338bush. of bananas, 26,641 bags of potatoes, 1,156 bags of onions, 86pkgs. of vegetables, and 29pkgs. of plants, trees, and bulbs, were examined and admitted, at Adelaide and Port Adelaide, under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910. Four hundred packages of bananas, 37bush. of pineapples (over-ripe), 98bush. apples (fruit fly), and 356 bags of potatoes (potato moth, etc.), were destroyed. Under the Federal Commerce Act, 367 cases of fresh fruits were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 25 cases grapes; for London, 12 cases apples; for Ceylon, 330pkgs. grapes. Under the Federal Quarantine Act, 1,809pkgs. of seeds, bulbs, plants, etc., were examined and admitted from oversea markets.

During the month of April, 1915, 18,677bush. of fresh fruits, 7,640bush. of bananas, 19,729 bags of potatoes, 2,248 bags of onions, 2,533pkgs. of vegetables, and 33pkgs. of plants, trees, and bulbs, were examined and admitted, at Adelaide and Port Adelaide, under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910. One hundred and twenty-eight packages of bananas (over-ripe), and 66bush. apples (codlin moth), 74bush. oranges (no certificate), and 165 bags potatoes (potato moth, etc.), were destroyed. Under the Federal Commerce Act, 3 cases of fresh fruits, 121pkgs. of dried fruits, and 27pkgs. seeds were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 27 cases seeds and 100pkgs. of dried fruit; for London, 3 cases apples and 21pkgs. of dried fruit. Under the Federal Quarantine Act, 2,154pkgs. of seeds, bulbs, and plants were examined and admitted from oversea markets.

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, May 12th, there being present Messrs. G. R. Laffer, M.P. (presiding), W. J. Colebatch (Principal of Roseworthy Agricultural College), A. M. Dawkins, F. Coleman, C. E. Birks, J. Miller, C. J. Tuckwell, T. H. Williams (Chief Inspector of Stock), C. J. Valentine, and G. G. Nicholls (Secretary).

### BINDER TWINE IN CHAFF.

A complaint was received from the Mount Bryan East Branch of the Bureau regarding the injurious practice of chaff merchants cutting up binder twine with hay, and pointing out that knots and other pieces of twine had been found in the stomach of a cow that had died. The Brinkley Branch had also written on the same subject, and the Mount Compass Branch had suggested that steps should be taken to make it compulsory for merchants to remove all binder twine from the sheaves of hay before cutting them up. It was decided to refer the communications to the inspector under the Chaff Act for a report.

### WIDTH OF WAGONS.

The Secretary read a letter from the Woodleigh Branch, in the Loxton district, in which it was mentioned that the Width of Tires Act had been found necessary in order to protect the metalled road, and requesting that something be done to govern the width of wagons, especially in sandy localities such as that, where the roads were extremely heavy. The Board, at the instance of the Chairman, decided to refer the letter to the Wynarka Branch, in whose hands were the arrangements for the Pinnaroo District Conference, with a suggestion that, if considered desirable, the subject should be included in the agenda paper.

### DISPOSAL OF WHEAT.

The Board was asked by the Coomandook Branch to consider a scheme of Government aid to farmers, with a view to the adoption of a more effective and profitable mode of storing and marketing wheat than the present method of storing with the merchants. It was decided to advise the Branch to prepare the outline of a scheme so that the Congress Committee might have an opportunity to consider whether it would be worth while to have the matter placed before the General Congress in September.

### DUTY ON CORNSACKS.

At the April meeting a proposal was received that the Board should take action in respect to the proposed additional import duty on cornsacks. The

Vice-Chairman (Mr. F. Coleman) said if the farmers got a good crop, and good prices due to the war, it was only reasonable to ask them to contribute to the revenue. Professor Perkins said the prices would be good, and he had heard of inquiries already. In view of the heavy expenditure occasioned by the war, taxes would have to come from somewhere. A tax on superphosphates was unreasonable, because it might interfere with production; but that was not the case with bags. Mr. Coleman agreed that this year perhaps the impost was necessary; but once a tax was imposed it was difficult to have it removed. The Board decided to take no action.

#### BRANDING SHEEP.

Mr. Williams stated that the Strathalbyn Branch desired to know where the buyer of sheep was to place his brand when his own position had already been taken by the seller? The Act provided four positions for the reception of brands, viz., on the top of the shoulder, the near ribs, the off ribs, and the rump. A man could not put his own brand on top of that already on the sheep. To effectively safeguard himself, he should secure from the auctioneer at the time of buying, a sale note describing the brand then on the animals. In addition, he might place a number—any of those from two to nine inclusive—on some conspicuous part.

#### FODDERS AND FORAGE CROPS.

Mr. Dawkins directed attention to the recently published statement by the Director of Agriculture, setting forth various food rations and their values, and expressed the opinion that everybody who had stock to feed should carefully study it. The Chairman then referred to the excellent paper on "Forage Crops in the South-East," read by the Director at the Conference at Mount Gambier, and suggested that printed copies of it should be distributed among all the Branches of the Agricultural Bureau in the South-East, and that the members should be specially requested to read and discuss the dissertation at their meetings. The suggestion was readily agreed to.

#### NEW BRANCH.

Approval was given to the formation of a new Branch of the Bureau at Murray Bridge, with the following gentlemen as members:—Joseph Pike, Richard S. Bell, Richard Higgins, Longhurst, Arthur Joyce, C. V. Sabben, John Raunsley, Oscar Jaensch, Nelson, Coulter, C. Stecker, Tink, Bidjarano, J. H. Lehmann, Boerke, F. W. Lehmann, E. C. Doenan, Arthur R. Hilton.

#### NEW MEMBERS.

The undermentioned gentlemen were approved as members of the Branches shown, viz.:—Lucindale—P. Burke, G. Burke, Paech; Sherlock—W. C. Burgess; Glencoe—W. Lehmann; Mount Gambier—W. Watkinson, G.

Madeley ; Mount Pleasant—W. T. Vigar, C. O. Royal, E. J. Tapscott ; Orroroo—W. C. Scott ; Milang—L. Simon ; Tatiara—J. Hunt, jun., A. J. C. Guy ; Claypan Bore—J. Glayton, J. McGuire, E. G. Lee ; Salt Creek—V. McNamara ; Millicent—D. A. Hannaford ; Watervale—F. Wohlfeil ; Mantung—L. Stewart ; Mindarie—Roy Shannon ; Berri—W. N. Chapple, W. R. Robbins, C. B. Kuss ; Two Wells—W. Rowe ; Glencoe—P. Ryan ; Halidon—L. Shepherd, C. Fisher ; Woodleigh—H. Ede ; Port Germein—K. W. M. Beisel, H. G. Davey ; Brinkley—P. Humphrey, F. White ; Monteith—R. Richter, W. C. Schumacher, G. W. Trotter, H. Crawford ; Port Pirie—A. R. Lines, F. Walsh, F. Jose, W. E. Martin ; Strathalbyn—F. Mitchell ; Koonibba—A. E. Payne, E. O. Dahl ; Wilkawatt—A. Bates ; Mount Compass—R. B. Carmichael, M. Jagers ; Arthurlton—O. V. Rudd, H. W. Crosby.

#### METHOD OF MARKING FRUIT CASES.

The method adopted by South Australian fruitgrowers for marking export fruit by stencilling is decidedly crude, and, says the Trade Commissioner, in a report dated London, March 19th, leads to no end of confusion in the docks at the time of discharge in order to sort out each owner's consignment. He adds:—"Past experiences have proved that it is almost impossible to obtain a correct delivery of any one particular mark owing to the difficulty experienced in reading the stencilling, particularly on the ends of hardwood cases. I have gone through the methods adopted by Californian and Canadian shippers to overcome this difficulty, and have forwarded out per the R.M.S. *Moollan* samples of the ends of cases which I have had collected on Covent Garden Market. It will be seen that the methods adopted by American shippers take the form of printed paper labels pasted on the ends of cases, and it only needs one visit to any of the leading fruit salesmen's bulk stores here to appreciate the excellent means which this method of marking presents for identification purposes. Some of the brands which I am sending out are, perhaps, too elaborate and expensive, but there would be no necessity to adopt anything as costly as the designs I am referring to. I was particularly struck with one known as the 'Red Diamond,' which for cheapness and utility should recommend itself to most of our local growers. In addition to this design, Canadian growers are adopting a single letter or design, such as the red 'Y,' the 'XX,' which are likewise easily distinguishable, and cost very little to print."

## AGRICULTURAL STATISTICS.

### RESULTS FOR SEASON 1914-15.

WHEAT PRODUCTION, 3,527,428 BUSHEL; AVERAGE, 1.41 BUSHEL.

The Government Statist (Mr. L. H. Sholl, C.M.G., I.S.O.) has issued the final results of the last harvest of cereal, hay, and fodder crops. The year 1914 eclipsed all previous records as a "drought year," and the exceptionally dry conditions, following as they did three comparatively dry seasons, played havoc with the prospects. In 1913 there was a low rainfall, with a remarkable absence of subsoil rains, and as a consequence, despite the improved methods of agriculture practised generally in the State, the various crops last year were more or less of a failure. The effect of the protracted dry period can be gleaned from the comparison of wheat production for the last two years. In 1913-14 16,936,988bush. were produced off 2,267,851 acres (of which 190,000 acres were an absolute failure), or an average of 7.47bush. In 1914-15 2,502,630 acres were sown for grain, and produced 3,527,428bush., or an average of 1.41bush. per acre. The hay yield in 1913 was 571,616 tons, and owing to the unfavorable conditions during the past season, the cut dwindled down to 153,738 tons, with an average of 0.48 tons per acre. This meagre production was insufficient for local requirements, but some satisfaction can be gained from the knowledge that such a phenomenally dry year is not likely to occur again for a long period if statistics can be relied on. The average annual rainfall in Adelaide for 76 years is 20.88in., and previous to the year 1914 the lowest fall was 13.43in., in the year 1876. The record last year was only 11.39in., being 2.04in. less than the previous lowest, and 9.49in. less than the average of 76 years. It is satisfactory to note that there was an increased production of 195 tons of lucerne hay, 5,969 tons being cured as against 5,774 tons in the previous season, thus showing that producers are beginning to more fully appreciate the virtues of this valuable fodder. The total conservation of straw of all kinds, on the other hand, was reduced from 17,134 tons to 6,484 tons, mainly on account of the short character of many of the crops, and also to the comparative failure of others. The total area of cultivated land fed off or cut for green fodder was 52,656 acres, including 15,083 acres of lucerne as against 49,948 acres, including 15,176 acres of lucerne in 1913-14.

Commenting on the season, the Assistant Government Statist (Mr. W. L. Johnston), who compiled the harvest returns, states that over the agricultural

areas of the State the average rainfall from April to September for the last 54 years was 14·68in., the lowest record being 6·20in. in the year 1902. For the year 1914 the average was 7·15in.

Below will be found details taken from the report :—

#### AVERAGE MONTHLY RAINFALL OVER AGRICULTURAL AREAS.

Showing the details for each month for the last five seasons and the average for 54 years :—

| Period.             | April. | May. | June. | July. | Aug. | Sept. | Total Six Months. | Oct. | Nov. |

| Mean for 54 years . | 1·71   | 2·55 | 2·96  | 2·80  | 2·53 | 2·13  | 11·68             | 1·78 | 1·09 |

#### ACREAGE UNDER CULTIVATION.

(Figures in parentheses are those for the previous season.)

The total acreage under all kinds of cereals for grain, hay, and fodder was 3,218,954 (3,104,366) acres, an increase of 114,588 acres. Counties Albert, Fergusson, Daly, Stanley, and Victoria all show large increases in the area sown.

*Wheat*.—2,842,020 (2,699,632) acres were sown, an increase of 142,388 acres.

*Barley*.—73,308 (94,039) acres were sown, a decrease of 20,731 acres.

*Oats*.—267,561 (273,718) acres were sown, a decrease of 6,157 acres.

The following table shows the distribution of the area sown in comparison with the previous season :—

| Division of State.         | Total Area under Cereal Cultivation. | Total area sown for all purposes with— |                    |                     |                    |
|----------------------------|--------------------------------------|----------------------------------------|--------------------|---------------------|--------------------|
|                            |                                      | Wheat.                                 | Barley.            | Oats.               | All other.         |
|                            | Acres.                               | Acres.                                 | Acres.             | Acres.              | Acres.             |
| I. Central .....           | 1,064,499<br>(1,016,732)             | 899,687<br>(841,439)                   | 44,738<br>(61,742) | 103,773<br>(96,623) | 16,301<br>(16,928) |
| II. Lower North .....      | 888,075<br>(809,946)                 | 830,845<br>(756,537)                   | 5,610<br>(5,470)   | 42,370<br>(38,220)  | 9,250<br>(9,719)   |
| III. Upper North .....     | 276,293<br>(290,059)                 | 273,901<br>(287,155)                   | 23<br>(211)        | 755<br>(974)        | 1,614<br>(1,719)   |
| IV. South-Eastern .....    | 421,102<br>(429,838)                 | 329,804<br>(328,704)                   | 15,281<br>(19,118) | 67,367<br>(73,967)  | 8,560<br>(8,049)   |

| Increase or Decrease ..... | + 114,588                            | + 142,388                              | - 20,731           | - 6,157             | - 912              |

## FAILURES.

*Wheat*.—1,246,799 acres, or nearly 44 per cent. of the 2,842,020 acres sown with wheat resulted in total failure. Of the 2,502,630 acres for grain only 1,307,666 acres were reaped, and of the 318,586 acres for hay only 266,751 acres were productive. Wheat was sown on approximately 14,500 of the 28,000 holdings for which returns were received. Only 8,200 of the wheat-growers reaped grain, and of these fully 3,000 reaped less than 100bush. each.

*Barley, Oats*.—The total failures for these crops were respectively 13,428 and 67,128 acres out of a sown area of 73,308 and 267,591 acres.

## FALLOW.

The total acreage of land placed in fallow during the season was 1,304,936 (1,569,623 acres, a decrease of 264,687 acres. When it is remembered that last season the sown area of 1,327,355 acres which resulted in total failure included large areas of fallow land the decrease just noted should not adversely affect the area likely to be placed under crop for the coming season. The good general rains which have just fallen will give an early start to seeding operations, and with the extra time thus available, even with the lessened horsepower, it is reasonable to expect that at least the same area will be placed under crop, and hence seed wheat requirements for 1915 have been estimated for 2,850,000 acres.

## PRODUCTION.

In the following summary of the various crops a comparison is made of the total yields and averages with those of the previous season :—

| Kind of Crop.         | Seasons.   |       |           |      | Decrease.  |       |
|-----------------------|------------|-------|-----------|------|------------|-------|
|                       | 1913-14.   |       | 1914-15.  |      |            |       |
|                       | Bush.      | Ave.  | Bush.     | Ave. | Bush.      | Ave.  |
| CEREALS—              |            |       |           |      |            |       |
| Wheat .....           | 16,936,988 | 7.47  | 3,527,428 | 1.41 | 13,409,560 | 6.06  |

| STRAW—                |            |       |           |      |            |       |
| All kinds.....        | 17,134     | —     | 6,484     | —    | 10,650     | —     |
| Wheaten .....         | 13,160     | —     | 4,446     | —    | 8,714      | —     |

*Wheat*.—The average on the area sown for grain was 1.41bush. per acre, but for the area actually reaped it was 2.70bush. per acre.

The production of wheat, barley, oats, and hay in the several divisions of the State was as follows :—

| Divisions.                | Wheat.                   | Barley<br>(all kinds). | Oats.                | Hay<br>(all kinds).  |
|---------------------------|--------------------------|------------------------|----------------------|----------------------|
|                           | Bush.                    | Bush.                  | Bush.                | Tons.                |
| I. Central .....          | 1,337,548<br>(5,035,986) | 205,687<br>(783,873)   | 167,919<br>(414,409) | 122,353<br>(291,435) |

## MANURES, SEED, AND FODDER.

Two million seven hundred and one thousand eight hundred and ninety (2,659,608) acres were treated with 96,812 (97,023) tons of artificial manure. Requirements for 1915 are estimated—Approximate stocks, November 30th, 1914, 1,800,000bush.; actual yield, 1914-15 crop, 3,527,428bush.; total available, 5,327,428bush. Home consumption (including Broken Hill) to November 30th, 1915, 2,820,000bush.; seed wheat for, say, 2,850,000 acres, 2,262,500bush.; total estimated requirements, 5,082,500. The balance on November 30th, 1915, is estimated at 244,928bush. On the 31st December, 1914, the farmers reported that they held on their farms 290,847bush. of old wheat, and 71,810 tons of old hay. The quantities for the previous year were 193,390bush. of wheat and 116,690 tons of hay.

The following tables show particulars of wheat culture in each division of the State for the seasons 1913-14 and 1914-15 :—

## POULTRY NOTES.

By D. F. LAURIE, Government Poultry Expert and Lecturer.

### THE FUTURE OF THE POULTRY INDUSTRY.

It is not necessary to make any extended reference to the disastrous effects of the late drought and the consequent high price and general scarcity of poultry foods. Breeders have been hard hit all round. Stocks have been sacrificed, and in some cases beginners were compelled to sacrifice plant as well as stock. Many, however, have retained the most valuable stock birds in the hope of obtaining good results in normal times. It is at present impossible to state what will be the immediate result of the wholesale sacrifice of so many poultry flocks. The markets are seldom reliable guides. Or it may be that in a small community there is a limit beyond which prices will not rise. Table poultry are very little dearer at present than they have been in recent years. As regards eggs, the price at the time of writing is 1s. 10d. in Adelaide, as quoted by the salesmen. This is by no means a record price, as it was reached in May, 1912, at a time when there were many more hens to lay the eggs. There is one point at issue where the producer and consumer (or more correctly the speculator) part company. I refer to the practice of pickling and cold storing eggs. As long as this practice continues so long will it be easy to control the market price of eggs during autumn and winter. The cause for this evil practice is obvious. As South Australia is the only State (except Queensland, in a small degree) which has an exportable surplus, our breeders should send all surplus eggs in the time of low markets to England. The eggs so sent will not be here in cold store and pickle tub to compete against fresh eggs in autumn and winter. The cold storage and pickling business is not necessary; it is a makeshift. The development of a big export trade oversea from September to December would so stimulate production here that there would always be plenty of fresh eggs available in the autumn and winter, and at present average prices. Moreover, the absence of cold storage eggs would prevent market manipulation.

### IS THERE AN OVERSEA MARKET ?

Vested interests have prompted some people to a loud outcry against seeking an oversea outlet for our surplus eggs. It was stated that there was ample demand in the other States; this was said in ignorance probably of the fact that there was great development in the poultry industry of every

Australian State and in New Zealand. In spite of these vaunted markets we have witnessed in recent times a return to low prices : and low the prices will be until oversea shipments are reorganised. It is monstrous to expect that the poultry industry should be strangled for the sake of a few speculators. England offers a splendid outlet for all our surplus eggs and poultry, and we should spare no effort in exploiting that market. The war in Europe has devastated Belgium and part of Northern France, from which parts enormous quantities of eggs and poultry were forwarded to the English and other markets. Then, again, Galicia, a province of Austria, is probably completely denuded of all poultry stocks. This country was one of the largest exporters of eggs to other European markets. Before the war began there was ample evidence of a general shortage in the supplies of eggs. Formerly the United States of America and Canada exported largely to England : but of late years the home demand has overtaken production. Of course, the extreme prices ruling in England recently made it worth while shipping from America. The average annual price paid for all eggs imported into England has steadily risen during recent years—just as predicted by me in this *Journal* some nine years ago. There is every prospect that for years to come eggs will be dear in England at the time our shipments will arrive. The experience gained in our early shipments will enable us to land the eggs in first-class condition. By relieving the local market during the period of greatest production we shall obtain a better average price for the year, and poultry-breeding will be on a sound footing as regards outlets and markets.

#### OPERATIONS MAY BE EXTENDED.

Operations may be extended to an almost unlimited extent. There should be no misgivings on the score of markets and prices. Common sense co-operation will be the order of the day. But in order to obtain the best results, the adoption of modern methods is imperative.

#### UTILITY STOCK.

One good result of the recent stringent times is the wholesale clearance of mongrels and old and unprofitable birds. Hundreds of first-class stock hens and male birds have been sold from the Parafield Poultry Station to farmers who had disposed of their old stocks and are establishing a small stud from which to breed large flocks when poultry foods are again plentiful. There is no reason why farm flocks of laying hens should not give an average annual egg yield of 170 eggs—the present average is about 85 eggs. If South Australian farms were restocked on this basis we should soon double our egg production and exports. The South Australian White Leghorn is unrivalled for egg production, and the eggs are of fine size. Some farmers object to the light breeds because they fly so much. But there is a remedy.

All farm poultry should sleep at night in houses surrounded by a high wire netted fence as protection from foxes. Therefore it is quite easy at times to cut the wings of the birds which are persistent flyers. There are the all-round breeds, such as Wyandottes, Orpingtons, and Plymouth Rocks, many strains of which are excellent layers, and all are superior to White Leghorns as table birds. As regards restocking farms, one of the functions of the State Poultry Station at Parafield is the development of utility strains of fowls and the breeding of large numbers of reliable stud birds for distribution among farmers. Those who contemplate establishing a new flock are notified that from about July to the end of September there will be available a few hundred first-class White Leghorn breeding hens and any number of first-class cockerels. Last season a large number of first-class early-hatched cockerels were distributed among members of the Bureau branches, and this year the good practice will be continued.

#### YARDS AND HOUSES.

The prevalence of foxes throughout the State has induced many farmers to provide fox-proof accommodation for their poultry flocks. There are some, however, who depend on the watchfulness of their dogs. Dogs are not ubiquitous, and sooner or later the foxes will triumph. Then on one night damage will be done far exceeding in value the cost of good yards. The value of good yarding and housing extends beyond mere protection from foxes, &c. The birds are under control in every way, and the farmer can gather the eggs daily, if proper nests are provided. This is a very important matter. The laying hens should be without male birds, so that only infertile eggs are produced. These should be collected daily, and sent to market as often as possible; at least twice a week. Plans of all descriptions of yards and houses are supplied gratis by the Poultry Expert to farmers. The system known as the "Farmers' Poultry Yard" is excellent, and is in great request. For those whose operations are more extensive plans of various buildings are also available. Has the reader built good yards and houses? If not, let him write for plans and particulars; they are free of all cost to him.

#### FOODS AND FEEDING.

While at the present time prices are high and foodstuffs scarce, it will not be long before conditions return to the normal. Farmers should, later on, make provision for their poultry by putting aside wheat, &c. If fed on wheat alone about  $1\frac{1}{4}$  bush. per year per adult fowl will suffice. If mash also is fed each fowl will require  $\frac{3}{4}$  bush. of wheat, 1 bush. of pollard,  $\frac{1}{2}$  bush. of bran, and about 60 lbs. of green food (chaffed). Meat should also be used, and, if meat meal, 5 lbs. per bird per year is ample. Each bird will need about 25 lbs. weight of sharp grit or gravel (including charcoal grit and shell grit).

## INCUBATION.

Many farmers have recourse to incubators for hatching eggs. As long as one can obtain a supply of fertile eggs incubator chickens can be hatched at any season. If, however, broody hens are relied upon, you must wait until a hen chooses to become broody, and that may be late in the year. Hatch all the chickens early. September for the North and Pinnaroo country is quite late enough; a month later in late districts. There are plenty of good incubators, including those made locally. Follow the instructions sent out by the maker. Many people place the incubator in a spare room in the house. The temperature of this room may vary considerably. It may be a very cold room, or it may be a warm one. Hang a thermometer in the room and run your incubator at the temperature corresponding, and as shown in the following table. The duration of the process of airing the eggs is also given.

| Average Room Temperature.<br>Degrees. | Operating<br>Temperature.<br>(Machine)<br>Degrees. | Airing Eggs.                         |                                                  |

| Hotter Days .....                     | 100-101 ..                                         | 20                                   | 30min. to 1hr.                                   |

Test the eggs on the seventh, twelfth, and eighteenth day for fertility and live chickens. Duck eggs are tested again on the the twenty-sixth day.

Do not handle the eggs if your hands are contaminated with kerosine or other substance.

Wash all dirty eggs before placing them in the machine.

Do not set travelled eggs until they have rested for 24 hours.

Select eggs of even size, and see that each egg is not less than 2ozs.

Keep the lamp scrupulously clean, and burn only the best kerosine. After lighting a lamp do not turn up the flame at once; do this gradually, and keep under observation for 10 minutes before leaving for the night or when going away from the house. If the lamp smokes there will be trouble.

Do not breed from pullets. Obtain second season hens mated with a first-class cockerel or young cock.

Eggs over a week old should not be placed in an incubator.

When the chickens hatch they require no food for 30 to 40 hours or more. Keep them warm, and later on let them scratch in clean sand or sandy soil. They may have clean water to drink.

Do not overcrowd the brooders. Over-heating is a cause of great loss. Encourage the chickens to run about and forage between meals. Feed them on finely-cracked wheat, &c. Give no wet mash until they are a month old.

If you have tick and other vermin in your poultry houses you cannot look for success; their presence means failure.

There is only one method of dealing with these parasites, and that is extermination. Do not be misled by "tick-proof" devices. If ticks and mites are on the premises they will manage to attack the fowls. The presence of tick on a farm should be viewed in its proper light, viz., as a reflection on the owner.

#### AGRICULTURAL BUREAU SOCIAL AT BLACKWOOD.

The annual social of the Blackwood Branch was held on April 15th, when there were present the Minister of Agriculture (Hon. Clarence Goode), Messrs. G. Jeffrey and G. G. Nicholls (member and secretary respectively of the Advisory Board of Agriculture), Mr. F. E. Place (Government Veterinary Lecturer), Mr. G. Quinn (Government Horticultural Instructor), and 130 members and visitors. The President (Mr. W. L. Summers) introduced the Minister, and extended a hearty welcome to the visitors.

The Minister, in responding, expressed pleasure at being present at that function of the Agricultural Bureau, as it was an institution in which he had considerable interest, because of his past association with the Gladstone Branch. It had been his privilege to act as member, Secretary, and President at different times. Social meetings were not unknown to that Northern Branch, but they usually took the form of smoke socials. The form of gathering arranged by the Blackwood Branch, including, as it did, the ladies among the guests, seemed to be a decided improvement. He was glad to take the opportunity of stating publicly that so long as he held the position of Minister of Agriculture he would do all in his power to further the interests of the Agricultural Bureau. The State had been passing through a very difficult period, but the Government were confident that the indomitable spirit of the people would carry them through successfully to more prosperous times. He sincerely hoped that much would be done in the future to take the fullest advantage of the natural resources of the State in respect of irrigation, and to provide a means of reducing to a minimum loss of livestock if or when periods of drought again visited South Australia. (Applause.)

Veterinary Surgeon Place delivered an interesting lecturette entitled "Ploughing an Eastward Furrow," in which he described some of the beauty spots of India.

The following exhibits were tabled:—Collections of birds and shells, Mr. E. Ashby; beetles, Messrs. S. H. Curnow and J. B. Harris; pressed ferns, Mr. W. L. Summers; pressed wild flowers, Miss Cheetham; microscopic specimens, Messrs. G. Quinn, E. Ashby, and C. G. Savage; crude tin, Mr. Harvey; and pictures, Mr. C. G. Savage.

Songs were contributed by Mrs. Tossach, Misses Scherer and Short, and Mr. F. R. Savage.

On the motion of Mr. G. Jeffrey, seconded by Mr. G. G. Nicholls, a vote of thanks was passed to the Minister, the local Branch, the performers, and the ladies' supper committee. The Minister and Mr. A. J. Penno responded.

## THE WHEAT MARKET.

| Date. | LONDON (Previous Day).           |
|-------|----------------------------------|
| May 6 | Firm; rather dearer.             |
| 7     | Firm.                            |
| 8     | Firm.                            |
| 11    | Firm; Liverpool market quiet.    |
| 12    | Dull; offered lower.             |
| 13    | Firm.                            |
| 14    | Easier.                          |
| 15    | Dull, easier tendency.           |
| 18    | Quiet.                           |
| 19    | Quiet.                           |
| 20    | Unchanged.                       |
| 21    | Dull; offered lower.             |
| 22    | Quiet.                           |
| 26    | Firm but quiet; Liverpool quiet. |
| 27    | Quiet.                           |
| 28    | Quiet.                           |
| 29    | Unchanged.                       |

As the cables indicate London wheat buyers have displayed little interest in the market, which throughout the month of May was generally quiet. The price of wheat in South Australia was quoted at 7s. 6d. per bushel for ordinary f.a.q. on trucks Ports Adelaide, Pirie, and Wallaroo at the beginning of the month, and that rate is still quoted, although practically no business is being done. The value of milling parcels remained steady at 8s. 4d. on trucks at Port Adelaide. In Victoria very little Australian wheat is procurable, and interest centres chiefly in importations from America, the price quoted being 7s. 11d. per bushel.

## DAIRY AND FARM PRODUCE MARKETS.

The Government Produce Department reports on June 1st:—The general production of butter is improving, and although the increase is gradual, the outlook is decidedly favorable. There has been a rise of 1d. per lb. in the price of butter, the present prices being—Superfine, 2s.; pure creamery, 1s. 11d.

A. W. Sandford & Co., Limited, report on June 1st:—

**BUTTER.**—The capital rains recorded during the month of May will give a great impetus to the dairy industry. Already supplies of butter are showing a slight increase as the result of the early rains in April. The supplies, however, are still very far short of local requirements, so that heavy importations continue to come along to meet the shortage. Values have advanced to the extent of about 1d. per lb. all round, and "Alpha" is now selling at 2s. per lb.; "Primus," 1s. 11d.; choice separators and dairies, 1s. 9½d. to 1s. 10½d.; well-conditioned store and collectors' lines, 1s. 5d. to 1s. 7d. lb.

**EGGS.**—In the early part of last month values firmed 2d. per dozen, but the high rates interfered with consumption, so that prices have dropped back 1d. Present quotations:—Hen eggs, 1s. 9d. per dozen; duck eggs, 1s. 10d.

**CHEESE.**—The absence of importations on this market caused a brisker inquiry for local makes, and South-Eastern consignments met with a brisk market; values closing at 11½d. to 12½d. for large to loaf.

**BACON.**—Owing to the shortage in live hogs importations of bacon have been made from New South Wales and Queensland to cope with the demand. Best factory-cured sides are selling from 10d. to 11d. per lb.; hams, 11d. to 1s. per lb.

**HONEY.**—The market has not been quite so active, although there has been no quotable alteration in values, prime clear extracted selling at 5d. per lb., and bees-wax at 1s. 4d. per lb.

**ALMONDS.**—Values have depreciated somewhat owing to importations from Sicily being placed in this State. Present quotations:—Brandis, 8d. per lb.; mixed softshells, 7d.; hardshells, 3½d.; kernels, 1s. 6d.

**LIVE POULTRY.**—Very active markets have been experienced throughout the month. This attracted a large attendance of the trade, and nice prices have been secured for all classes offering. Heavy weight table roosters fetched 3s. 6d. to 4s. each; nice-conditioned cockerels, 3s. to 3s. 6d.; plump hens, 2s. to 2s. 6d.; fair-conditioned hens and light cockerels, 1s. 4d. to 1s. 9d.; ducks, 2s. 6d. to 3s. 6d.; geese, 4s. to 5s.; pigeons, 5d. to 6d.; and turkeys from 7d. to 11d. per lb. live weight for fair to good table birds.

**POTATOES AND ONIONS.**—There has been an active demand for potatoes, but the bulk of requirements have been drawn from Victoria. Onion supplies are lighter, and consequently prices have improved. Present quotations—Potatoes, £6 10s. to £7 per ton of 2,240lbs. on trucks Mile End or Port Adelaide. Onions, £6 10s. to £7 10s. per ton of 2,240lbs. on trucks Mile End or Port Adelaide.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of May, 1915, also the average precipitation for May, and the average annual rainfall.

| Station.                   | For May, 1915. | Av'ge. for May. | Total to end May. | Av'ge. Annual Rainfall | Station.               | For May, 1915. | Av'ge. for May. | Total to end May. | Av'ge. Annual Rainfall |

\* No report received during the month of May.

† Formal report only received.

‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

### June 9th, and July 14th, 1915.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

Edited by H. J. FINNIS.

#### UPPER-NORTH DISTRICT.

(PETERSBURG AND NORTHWARD.)

AMYTON, April 23rd.—An address upon dairying was delivered by Mr. H. J. Apps, who described the various breeds of cattle, and advocated herd testing. Many questions bearing on the comparative feeding values of fodders were satisfactorily answered.

CARRIETON, April 29th.—The Secretary explained that the reason for the postponement of meetings during the preceding half-year was "droughty conditions." Mr. G. Fuller moved, and Mr. E. W. Radford seconded a motion, which was carried, that the Branch were in favor of a general petition to the Federal Government requesting the reduction of duty on cornsacks.

WEPOWLE, April 27th.—There was a good attendance, and a profitable discussion followed the reading of a practical paper on "Horses," prepared by Mr. J. Burns.

WIRABARA, April 24th.—An instructive paper dealing with practical bee-keeping was read by Mr. P. J. Curnow. Messrs. H. Jericho and H. E. Woodlands congratulated the writer.

#### MIDDLE-NORTH DISTRICT.

(PETERSBURG TO FARRELL'S FLAT.)

BEAUFORT.

March 25th.—Present: 10 members.

SUPER. AND STABLE MANURE.—Mr. A. Yard read a paper entitled, "Mixing of High-grade Super. with Farmyard Manure." He believed that it would prove profitable, as by mixing from 10lbs. to 20lbs. super. per acre could be saved, or one ton in five. Mr. G. Underwood said stable manure should be placed in an old dam to rot before being distributed or mixed with super. Mr. J. Sampson thought that sheep manure was better than stable manure for mixing with super. The idea at first was to make the super. run more freely. Mr. S. Underwood said the saving would not pay for the cost of labor. He favored carting the stable manure, when well rotted, straight out to the paddock. Messrs. C. Veitch, C. Wilson, P. H. Underwood, and W. W. Mugford also contributed to the discussion. Members generally favored high-grade supers.

BOOLEROO CENTRE (Average annual rainfall, 15.23in.).

April 27th.—Present: 13 members.

PRODUCING PIGS FOR MARKET.—Mr. J. Carey, sen., said the Berkshire was the most satisfactory breed, as it stood the hot weather better than any other, fattened well, and produced flesh of good quality. It did not pay a farmer to

breed young pigs for sale in the open market. There should be sufficient feed on hand, or a prospect of getting it cheaply, to enable the breeder to hold the pigs until they were ready for sale to the butcher or bacon manufacturer. A long, roomy sow, with broad loins, should be selected for breeding purposes. The suckers should be weaned when eight weeks old, when they could be fed on pollard, milk, and soaked wheat. He preferred soaked wheat to boiled wheat. Green feed at intervals and plenty of exercise were required. At first food should be given at short intervals, and meals should subsequently be reduced to three regular feeds per day. In eight or nine months the young pigs could be marketed as fat porkers. Messrs. W. Whibley, W. H. Nottle, sen., and W. Michael contributed to the discussion that followed. Members generally held the opinion that the unfavorable conditions for dairying in the district made it unprofitable to keep pigs, except for home consumption.

#### CANOWIE BELT (Average annual rainfall, 20.04in.).

April 14th.—Present: 13 members and three visitors.

**SEEDING.**—Mr. R. Carter read an interesting paper on this subject. His method of pickling was to dissolve 6lbs. of bluestone in 60galls. of water and immerse the wheat in bags, slacked to allow of the swelling of the grain, for three minutes. The most consistent wheats for the district were Yandilla King and Federation. Barley and oats did well in the district, and were useful in providing green feed and grain for stock. He used 70lbs. of seed and 60lbs. of super. to the acre. In normal seasons the seeding should be finished by the end of May. Messrs. Kirk, Bray, Noll, Sparks, Sanderson, and Wedding took part in the discussion.

**FODDER SUPPLIES.**—Mr. G. A. Young considered that every farmer should keep two years' supply of hay on hand. Straw should be cut with the binder immediately after harvest. Mixed with hay in the proportion of one to two parts, it made good chaff. Salt and molasses were a makeshift substitute when pollard and bran were not procurable. Messrs. Noll and Carter also spoke.

**GENERAL.**—A paper entitled "Things Generally Agricultural," was read by Mr. Joel Sparks, who gave some practical hints to young farmers starting on new selections. Referring to implements, he said the stump-jumpers were useful for breaking up new stony or tussocky land, but after that operation he would give them a back seat. He preferred the disc stump-jumping ploughs and cultivators, because they pulverised the soil better, and left a good seed bed. A set of discs would last half a dozen years. Scarifiers and cultivators should have a triangular harrow of light pattern to drag behind to level off the ridges and leave a good seed bed for the drill. He condemned the imposition of a duty on cornsacks.

#### CANOWIE BELT (Average annual rainfall, 20.04in.).

May 17th.—Present: 14 members and three visitors.

**SEEDING OPERATIONS.**—Mr. E. W. Noll read a short paper on this subject. He described his methods of cultivation. He considered 75lbs. of seed, with from 45lbs. to 60lbs. of super., sown to 2in. to 3in. deep, was sufficient for each acre. For dry sowing shallow drilling was preferable. Stubble land should be cultivated before cropping. Messrs. Kirk, Dowden, Daly, and Redden favored fallowing from 4in. to 6in. deep, as the land in the district would stand continuous deep ploughing. Seed put in to a depth of from 1in. to 1½in. was the most satisfactory. Mr. A. Noll said shallow ploughing had given the best results on his farm.

**MANAGEMENT OF FARM HORSES.**—This subject was dealt with by Mr. L. Kitchke. He advised good stabling, good feeding, and cleanliness in the stable yard. Horses should be watered before being fed. Teams should be stopped at sundown, as otherwise they were liable to catch cold in cooling off. Mr. E. L. Daly said he had found changing collars from one horse to another effective in curing sore shoulders. Mr. Kirk gave new collars a thorough soaking before placing them on the horses. The collars then shaped themselves to the animal's shoulders. His team had not been troubled with sores.

**PICKLING WHEAT.**—Members generally agreed that 1lb. bluestone to 10galls. water made an effective mixture, and that immersion of bags, if slack, for 1min. to 1½min. was sufficient.

**PORT GERMEIN** (Average annual rainfall, 12.84in.).

April 17th.—Present: 11 members and two visitors.

**PICKLING WHEAT.**—In introducing this subject, Mr. Hillam stated that to prevent smut he had found bluestone the best solution. He preferred placing the wheat gently in a vessel filled with pickle, so that the smut balls would rise to the surface, where they could be skimmed off. Mr. Blasing said he was trying a similar method. Messrs. Hackett, Deer, and Teasdale described their experiences. Mr. McDougall used 1lb. bluestone to 2galls. or 3galls. of water to pickle three bags on the floor. He had no smut. The Secretary (Mr. J. Stewart) suggested that members should tabulate their pickling results for a series of seasons, supplying the following particulars:—Variety, pickling recipe, area, date of sowing, climatic conditions at seeding time, state of season, comments on growth, harvesting record, and agents' prices. It was decided to adopt the suggestion.

**PORT PIRIE** (Average annual rainfall, 13.21in.).

March 20th.—Present: eight members and two visitors.

**SEEDING AND FALLOWING.**—Mr. T. G. Kirchner read a paper on these subjects. He favored early sowing, say, after the first of May, and after a rain, if possible. Rain was especially useful when seeding sandy land, as it prevented drift. Generally he preferred sowing early for hay, and later for grain, but it was difficult to say exactly what was the best time, as experience during the past two seasons had demonstrated. In 1913 the later sowings were the best yielders of grain, while in 1914 the early sowing produced the crop, and the late sown areas were an absolute failure. He considered, taking one season with another, that early sowing would be the best for wheat and hay. He also favored early sowing for oats and barley, especially when intended for green food. Cultivated lands sown for early feed produced feed much earlier than grass land, and feeding it off helped to reduce the weeds. Sandy stubble land, without any previous preparation could be drilled with early feed crops. Rape and barley was a satisfactory mixture to sow on sandy land to provide feed for lambs and ewes. Fallowing operations should be commenced as soon as seeding was completed. One acre of good fallow was worth two of any other ground. On light land it was sufficient to plough 2½in. deep, and on heavy clayey soils from 3½in. to 4in. When the ploughing was finished, harrowing should be given to provide good conditions for the germination of weed seeds. The cultivator should be used before the weeds became too strong. The land should be harrowed again before seeding to provide a good seed bed. A discussion followed, and Mr. A. Lines said he thought that in dry districts shallow cultivation gave the best results.

**WHYTE-YARCOWIE** (Average annual rainfall, 13.91in.).

April 26th.—Present: 14 members.

**HAND-FEEDING SHEEP.**—A paper on this subject was read by Mr. G. McGregor, who referred particularly to this class of work on the small farm. In 1914 he hand-fed sheep from April 28th to November 26th. After three months feeding the sheep could have been sold at a good profit. The feed used was cocky chaff, hay chaff, and a little wheat. About one part of cocky chaff was mixed with two parts of hay. It was a good plan when commencing to feed to place the sheep in a small paddock where there was water, but no feed. He had found that old ewes in poor condition reared their lambs better when oats were substituted for wheat, and was fed with the chaff. Some dry ewes were good mutton in less than two months, but wethers, ranging from 2-tooth to full mouth, were not fit to kill until they had been fed for six months. The average quantity of food given in July and August, when there was no herbage in the paddocks, was 1½lbs., including ½lb. of wheat, to each sheep per day. Altogether 17 tons 13cwts. of chaff and 84bush. of wheat were consumed. The sheep cost 9s. 1d. per head when purchased, and the hand-feeding cost 7s. 4d. per head, or 1s. per month for each sheep. These estimates did not include the lambs, whose feed was reckoned in with the sheep. The sale of the wool and 120 sheep and lambs returned £5 more than the original cost of the whole of the sheep, and as a set-off against the feed 103 picked sheep and lambs were retained. Hand-feeding for about three months in a normal year would enable the farmer to double the sheep-carrying capacity of his holding. Mr. G. F.

Jenkins preferred bran and oats to wheat for mixing with chaff. Mr. E. J. Pearce thought that wheat, chaff, molasses, and bran was an ideal food. Mr. J. E. Hunt said hand-feeding should not be allowed to absorb necessary fodder reserves. Mr. G. P. Mudge also spoke.

#### YONGALA VALE (Average annual rainfall, 13in. to 14in.)<sup>a</sup>

May 1st.—Present: 10 members and one visitor.

**FARM TOOLHOUSE.**—Mr. T. D. Keatley made some suggestions. He advocated stocking the toolhouse with a blacksmith's outfit and other tools. He described a simple drawer to hold bolts, &c., made of an oil case and petrol tins, with one side cut out.

**CONSERVATION OF HORSE FEED.**—A paper dealing with this subject was read by Mr. E. Fowler, who said a farmer cropping from 250 to 400 acres annually, and maintaining from 15 to 20 horses, should cut no fewer than 80 to 100 tons of hay. This would leave a stock of 40 to 50 tons available at the next hay season, when the reserves should be increased. He advocated feeding hay to stock in racks or mangers, as throwing it on the ground resulted in much unnecessary waste. The mixture of a little cut straw chaff helped to eke out hay supplies in times of scarcity. Every farmer should build a straw stack and hold it in reserve. In cold weather it could be fed to cattle, either loose or with molasses. Cocky chaff should be saved, and a supply of oats be maintained. Mr. F. Miller considered that there was no need to use ordinary strippers to save cocky chaff, as the carriers attached to harvesters were effective. Mr. Battersby thought straw chaffed with the hay was a more valuable and economical food, and to keep large quantities of hay on hand was not necessary once in 50 years.

**BOOBOROWIE, April 23rd.**—The Dairy Expert (Mr. P. H. Suter) delivered a comprehensive lecture on "Dairying." He strongly urged owners to test, feed, and cull their herds, and use bulls whose ancestors had been heavy producers of rich milk.

**MOUNT BRYAN EAST, April 24th.**—Members complained that chaff merchants were cutting up binder twine with their hay. A post-mortem examination of a cow had revealed knots and pieces of twine in the stomach.

**PORT BROUGHTON, April 30th.**—The subjects of co-operation and veterinary medicine chests were discussed, and consideration of them was adjourned till next meeting.

**PORT PIRIE, February 27th.**—Mr. A. Bond read a practical paper on "By-products of the Farm." Messrs. F. Johns, J. Greig, E. B. Welch, T. G. Kirchner, and A. M. Lawrie contributed to the discussion.

**REDHILL, April 29th.**—Members discussed co-operation and generally agreed that farmers could combine with advantage in the purchase of manure, machinery, &c.

**SPALDING, March 19th.**—**THE NORTHERN TERRITORY.**—At the request of members Mr. V. W. Holland described the Northern Territory, and related his experiences there.

**SPALDING, April 24th.**—A discussion on fodder growing and hand feeding sheep was initiated by the Chairman (Mr. A. B. Jones). An instance was given where one station, at Wagga, New South Wales, annually fed from 15,000 sheep to 20,000 sheep daily during the dry period with less than 2lbs. of silage and  $\frac{1}{2}$ lb. of oats per head, distributed in wooden troughs. As a result the stock were safely carried through a drought, and a good supply of early lambs was produced for the export trade.

### LOWER-NORTH DISTRICT.

#### (ADELAIDE TO FARRELL'S FLAT.)

**ANGASTON** (Average annual rainfall, 22.25in.).

April 24th.—Present: 17 members and two visitors.

**CO-OPERATION.**—It was unanimously decided to support the scheme of co-operation suggested by the Clare Branch at the Bureau Congress in September.

**LESSONS OF THE DROUGHT.**—An informative paper was read by Mr. J. P. Richardson. He dealt specifically with lessons learned during the recent drought. They had to be careful not to overstock, to always have a surplus of feed, and to store a reserve of fodder. He recommended early ploughing after the first rains in the orchard and vineyard, and leaving the land fairly rough, to absorb maximum moisture, till spring, when cultivation would retard evaporation. To facilitate spraying and pruning alternate rows could be left unploughed until those operations were completed. Ploughing should be from 6in. to 8in. deep, except in old orchards, where roots were near the surface. He gave some advice regarding the preparation of stubble and fallow land for cereal crops, and advocated sowing barley on the former class to produce feed in the winter and grain in the late spring. Barley choked out the weeds better than either wheat or oats. He intended sowing fodder crops in the orchard for the dual purpose of grazing sheep and subsequently ploughing under as green manure. Thorough tillage was necessary in the preparation of land for forage crops. Cereals were profitable, but he preferred barley for growth and capacity to stand feeding down. On sandy land rye was recommended. He sowed barley at the rate of from 1bush. to 1½bush. of seed to the acre, with 1cwt. of super. A trial should be given broad-leaved Essex rape, shallow-drilled at the rate of 4lbs. or 5lbs. of seed to the acre, with ½cwt. of bonedust. If possible the seed should be sown not later than the end of March. If broadcasted, 6lbs. to 8lbs. of seed should be used to the acre, and it should be distributed over a rolled surface. A mixture of 4lbs. rape, 40lbs. to 50lbs. barley, and 1½lb. mustard to the acre made a good forage crop. The Jersey kale and thousand-headed kale were also useful. He preferred the latter variety. Kale required a strong soil, cultivated 6in. to 8in. deep; 1lb. of seed with 56lbs. of bonedust should be drilled in in rows 24in. to 30in. apart, as shallow as possible, at the end of March or the first week in April. The crop would be ready for feeding off by September, and could be fed off from time to time subsequently as growth permitted. There were possibilities in the cultivation of turnips, mangolds, vetches, peas, and the various grasses and clovers. He quoted the results obtained at Roseworthy College in the production of kale and berseem for stock. For summer forage he recommended lucerne, maize, sorghum, and millet. He advised sowing the three last named in rows 24in. to 30in. apart, at the end of September, as follows:—Sorghum, 5lbs. to 7lbs. of seed to the acre; millet, 4lbs. to 5lbs.; maize, 20lbs. He mixed bonedust with the sorghum and millet, and applied 1cwt. super. with the maize. Big returns could be secured with irrigation. An acre plot at Roseworthy, sown in early autumn with berseem, and again in spring with sorghum, returned 34 tons and 20 tons of the respective fodders in one year. Lucerne under irrigation was of immense value as a fodder, and a few pounds sown with the cereal crops improved the grazing properties of the paddocks.

**BLYTH** (Average annual rainfall, 16.46in.).

February 13th.—Present: 10 members and one visitor.

**STABLE MANURE.**—Mr. A. L. McEwin said it was a problem to successfully deal with stable manure. It was his practice to place it on the land and fallow it in. He invariably found, however, that the resulting crop was the dirtiest, the poorest, and the most costly on the farm. He suggested that it might be possible to store the manure in a depression, and when it was well rotted to truck it away in bags to the hills districts, where it was a valuable aid to production. Stable manure benefited sandy or stiff clayey soil, and was also valuable on limestone rubble land, but it was a drawback on all heavy cereal soils in light rainfall country, say from 18in. downwards. For gardeners and irrigationists the manure could not be beaten, but it was not a profitable proposition for the agriculturist on the plains, where there was only a medium rainfall. The cost of handling it was expensive, but the farmer had to deal with the accumulations, and the most efficient method was to cart direct from the stable to the paddock, and either plough it in or leave it as a top-dressing on grass land till the following winter.

**BLYTH** (Average annual rainfall, 16.46in.).

May 1st.—Present: 11 members and two visitors.

**FEEDING HORSES.**—Mr. W. O. Eime read a paper on this subject. He said molasses fed in the latter part of the summer or autumn was a splendid thing

for horses that had had nothing but dry feed for months, as it loosened their bowels and assisted to shift accumulations of sand. A mixture of molasses and cocky chaff or good straw chaff might keep horses fit for light work, while molasses thrown over straw might keep the animals alive. However, it paid better to use good hay chaff. The addition of straw or cocky chaff was advisable in times of scarcity. Cocky chaff was invaluable as a standby. He did not place much faith in straw chaff, which should be put through the winnower, so that only the parts blown out were used. The straw chaffed in the usual way sometimes resulted in the death of animals. Horses in the district did not get enough salt. They could not get enough off the rock salt. He believed it advisable to give a handful of coarse salt in the feed for a week or two at intervals. The best feed for working horses was lbush, crushed wheat to each bag of rolled oats. For eight horses in solid work he gave a bushel of the crushed grain with four branbags of good hay chaff daily, and at night two sheaves of hay were given for each animal. He found that horses eat quicker and better when the hay chaff was not dampened, either when cutting or feeding. Horses should be watered when ready to go out to work, and upon their return, but should not be allowed free access to the water trough during feeding. Despite the high price of fodder farmers should give the working horses the best feed they could. Mr. McEwin believed in storing 12 months' supply of hay. He only believed in conserving straw by stacking it in the paddocks for stock to pull at their desire. The idea of using coarse salt instead of rock salt was a good one. One gallon of corn to each horse daily in good hay chaff was too much. He believed in having the water trough in the feed yard. Messrs. J. T. Harmer and J. Pratt also joined in the discussion.

#### CLARE (Average annual rainfall, 24.30in.).

April 30th.—Present: 22 members and two visitors.

**PRUNING MATCH.**—It was decided to hold a pruning competition at Mr. W. Pattullo's orchard and vineyard on the first public holiday in June. The following committee was appointed:—Messrs. C. T. Jarman, R. Hunter, J. H. Knappstein, W. Pattullo, F. Hicks, and C. J. Radford.

**ROTATION OF CROPS.**—This subject was dealt with in a lengthy paper by Mr. W. G. Lewcock, sen., who dealt exclusively with the preparation of land and rotation of crops in the south-west of England, some 30 to 40 miles from London, as he remembered it from 1854 to 1867. Several members discussed the paper, and hoped that Mr. Lewcock would write a paper on the same subject as it applied to their own district.

#### JULIA (Average annual rainfall, 18in. to 19in.).

May 14th.—Present: eight members.

**SEEDING OPERATIONS.**—Mr. B. J. Schmidt dealt with this subject. He considered that sowing the seed from the middle of April to the middle of May was necessary in that district to get a good return. However, sooner than dry-sow he would cultivate the fallow deeply, and wait for rain. In wet weather, harrowing should follow the drilling, as otherwise the grain would lie too loosely in the soil. He sowed from 70lbs. to 75lbs. of seed to the acre, and obtained the best results with early varieties by using the maximum quantity, with 100lbs. of super. To secure grain crops he sowed late wheats early and early varieties late, but if hay was required, he cross-drilled in early varieties, using 45lbs. seed and 56lbs. super. each way.

#### MALLALA (Average annual rainfall, 16.88in.).

April 6th.—Present: 14 members and one visitor.

**SUCCESSFUL FARMING.**—Mr. H. Jury read a paper on this subject. He recommended fallowing as soon as seeding was completed, ploughing firm land with many weeds, and cultivating loose land. Ploughing 4in. deep was advisable on land well soaked with winter rains, but 3in. was sufficient on drier soils. Harrowing once each way, after ploughing, was necessary. Subsequent weeds should be fed off with sheep, and finally cultivated out. Harrowing should

be given after each rain. Land intended for fallow could be cultivated after harvest, so that weeds would germinate with the first rains. He sowed stubble land for a hay crop in April. If the soil was dry, he did not harrow after the drill, but waited for the rain before carrying out that operation. He preferred sowing on fallow after a rain. When sowing dry he put the roller over the ground before drilling to prevent the seed going in too deep. If the fallow was wet he cultivated it as shallow as possible before drilling in the seed. If weeds were numerous, harrowing before and after the drill was necessary. He sowed early wheats or oats first on stubble land, and late wheats first on fallow. He waited for 10 days after the first autumn rains before cultivating dirty fallow, in order to allow time for the weeds to germinate. He sowed wheat dry on stubble land for hay, but pickled all wheat for sowing after rains. He believed in rolling the wheat crops soon after germination, especially those intended for hay. Members generally agreed with the writer. Mr. R. C. East advocated the use of the spring-tooth cultivator in preference to the set tine, and light harrows, about  $\frac{3}{4}$  in. square, for harrowing growing crops.

#### NORTHFIELD (Average annual rainfall, 19in.).

April 13th.—Present: six members.

**HANDLING YOUNG HORSES.**—Mr. D. Rowe (Vice-President) read a practical paper dealing with this subject. He pointed out the fact that the small farmer labored at a greater disadvantage than a breeder in a large way, as he was obliged to patronise travelling sires, whose progeny sometimes developed serious deficiencies. The drawback resulting from this disability was realised when the time came to handle the youngster. The head might be too large, the neck too thin, the shoulders without muscle, and the conformation generally at fault. Defects such as enumerated made the work of fitting the unbroken animal with suitable harness more difficult. Foals, he said, should be handled when a few days old. They should early be accustomed to having their heads handled or fondled. He did not hold with the method of tying, say, a three-months, six-months, or 12-months old colt to a post and allowing it to pull, without any controlling influence. He preferred using the headstall, the top of which should not be allowed to pass the first joint of the neck. The colt should be allowed to jump about. When tying the novice up to a post the rope should be kept near the bottom of it, so that the animal would not subject itself to so severe a strain. He should have his legs handled before being tied up, and should be taught to lead properly. It was important to secure good-fitting collars. If the top of the shoulder was thin, the collar was apt to pull too far back on the bones of the shoulder, but if thick and deep, satisfactory fitting was comparatively easy. When first harnessed the youngster should be coupled with an older horse, fitted with collar and hames. They should be hitched to a post attached to a swing and chains, without a backband, and be driven round. The rope on the headstall of the colt should be tied to the collar of the experienced horse, as this prevented him from standing to kick. An attempt to be unruly should be punished lightly with the whip, and the horses should be urged on, so that the colt would be forced along by his team mate. Finding that he was powerless to halt and kick, it would be only a matter of 15 minutes or 20 minutes before the colt would learn his lesson. Mr. J. Williams said he preferred leaving the foals alone until they were old enough to be broken to work. He thought a halter was generally safer to use than a rope, but if there was any trouble he advocated putting on a Professor Hyland's breeching. A good-fitting collar, rather on the tight side, was preferable to a loose one. Mr. A. Low believed in handling foals when quite young. He had never seen any ill effects from the practice during a long experience in Scotland. Mr. W. J. Dall did not favor the handling or tying up of foals. He had found that those not handled when young became the best workers. When breaking colts, he tied them to a post with a rope, and put on halters. He never allowed them to choke down or break a rope. They were not handled with older horses, but were put in a wagon and driven. They led better when trained by themselves. Mr. E. Kester supported Mr. Rowe's remarks concerning tying up of young horses.

**SALISBURY** (Average annual rainfall, 18.57in.).

April 6th.—Present: 13 members and two visitors.

**WHEAT AND MANURE TESTS.**—The Secretary (Mr. Arnold Jenkins) read the results of the tests carried out in 1914-15, as follows:—

| Variety.             | Condition when cut.                      | Weight.  | Equivalent per acre. |
|----------------------|------------------------------------------|----------|----------------------|
| Cumberland .....     | Good                                     | 203lbs.  | 14cwt. 86lbs.        |
| Gluyas .....         | Good                                     | 213lbs.  | 15cwt. 24lbs.        |
| Triumph .....        | Turning ripe                             | 189½lbs. | 13cwt. 60lbs.        |
| American No. 8 ..... | Unfit                                    | —        | —                    |
| Firbank .....        | Little over-ripe,<br>damaged by sparrows | 186lbs.  | 13cwt. 32lbs.        |
| Crossbred 53 .....   | Unfit                                    | —        | —                    |
| Genoa .....          | Unfit                                    | —        | —                    |
| Thew .....           | Right                                    | 195lbs.  | 13cwt. 104lbs.       |

In each plot, covering an eighth of an acre of well-prepared fallow, 11lbs. of seed was sown on May 12th. The germination in each case was even. The crops were cut on October 6th, and the stooking was done two days later. Ten manurial tests were carried out, but owing to the dryness of the season there was no appreciable difference in the results.

**LESSONS FROM THE DROUGHT.**—Mr. Bagster read a paper on this subject, strongly advocating the conservation of water and fodder. He believed in keeping as much stock on the farm as it could fairly carry. If the advice of some newspaper farmers—to stock only up to the capacity of a bad year—was followed, they might as well take the wires out of their fences and turn them into hoops.

**SALISBURY** (Average annual rainfall, 18.57in.).

May 4th.—Present: 11 members and one visitor.

**BERRI AND LOXTON.**—Mr. E. Moss described a recent visit to these places. At Berri, on account of the dry season and the low river, he was surprised at the vigor of the young orchards. The irrigated blocks presented a striking contrast to the adjacent scrub lands, which were barren of feed. Settlers were faced with a problem in procuring supplies of fodder, for although they could grow it, they had not been installed long enough to give this important matter the attention it merited. It was a wise plan for the newcomer, when laying out his block, to reserve from 2 acres to 5 acres for fodder growing, and to sow some lucerne as soon as possible after occupation. Most kinds of deciduous fruits and oranges grew to perfection, but apples and prunes were still under trial. Vegetables thrived wonderfully, but to overcome the drawback occasioned by the six-week intervals between irrigations, storage tanks had been found necessary. However, even with the ordinary irrigations potatoes and tomatoes gave heavy yields. He considered the ideal size of blocks for settlers not overburdened with capital was 15 acres—10 acres for fruits and 5 acres for fodder growing, drying green, and yard purposes. The water in the River Murray was too saline at present to be pleasant to drink, but the trees did not show any ill-effects, although some vegetables had suffered. At Loxton the scarcity of feed was noticeable. Old horses were dying, but young stock appeared to be holding their own remarkably well. Some farmers had been seeding for some weeks, and the wheat was springing evenly on the sandy land. With fair rains there were prospects for a record harvest. A discussion followed.

**TWO WELLS** (Average annual rainfall, 16.36in.).

January 26th.—Present: nine members.

**CULTIVATION OF LUCERNE.**—This valuable legume, said Mr. W. J. Hart, in introducing the subject, has undoubtedly established its claim to the title, "King of Fodders." The milk-producing and fattening qualities of this fodder have made it popular in every district where it can be grown successfully. Every farmer, he said, should try to establish a plot, even if the area available was limited to one-quarter of an acre. Land for the purpose should possess good drainage, and should not contain too high a percentage of clay or salt. The ideal soil was a fairly deep loam of a sandy rather than a clayey character. The area to be sown should be given a good dressing of stable manure, and be

fallowed with the plough at least three months before seeding it. Ploughing should be as deep as possible without bringing to the surface the subsoil, which, however, could with advantage be loosened up with a scarifier. The surface required working to a fine tilth with the harrows. Prior to sowing the plot should be rolled. The seed should be distributed, harrowed in, and then rolled again to secure a firm seed bed. The soil should hold enough moisture to germinate the seed and carry the plants into the fourth leaf at least. He broadcasted the seed at the rate of from 20lbs. to 25lbs. per acre. The best time to sow was in September, when no "nurse" crop was required. The cuts should be made when the plants were about one-tenth in bloom. After the first cut a light mulch of stable manure should be applied. Another dressing, the fresher the better, should be given after the third cut. Artificial manures were not recommended for use in the growing period, but they could be advantageously worked in with stable litter during the winter. The sprinkler was the best medium for watering. The best variety was the Hunter River, but to ensure purity a guarantee should be asked for when purchasing the seed. The Arabian variety did well in cold weather. The Turkestan was about the best for shallow soils or for grazing, and sown with the wheat crop at the rate of 3lbs. or 4lbs. to the acre, it would improve the stock-carrying capacity of the land. Where underground water supplies were not available it would pay the farmer to establish a small plot with Barossa water (available at 6d. per 1,000galls.). A plot half a chain square would require 2,000galls. to thoroughly soak it and start the growth. With little more water a cut should be produced every eight weeks. The Chairman and Messrs. Kenner and Frost contributed to a profitable discussion.

**FREELING, March 24th.**—"Road-making and Permanent Maintenance," was the subject of a paper read by Mr. August Mattiske, sen. A good discussion followed.

**GAWLER RIVER, March 31st.**—**COST OF FEEDING COWS.**—Mr. G. Higgins related his methods of maintaining a herd of nine cows for a year. He estimated the cost at £6 10s. per head per annum.

**LYNDOCH, April 29th.**—Mr. H. Kennedy reported that he had secured 150 signatures to a petition protesting against the 10 per cent. duty on jute goods. A discussion on bird pests took place, but no finality was reached. Correspondence dealing with co-operation was read, and the subject was reserved for discussion at the next meeting.

**MALLALA, May 3rd.**—**FARM LIFE.**—Mr. R. C. East said farm life should be made more attractive to keep the young folk on the land. The surroundings of the home could be improved in many cases. Farmers had scope to raise the standard of machinery by inventing or suggesting improvements. He reminded farmers that it paid to stack hay as a precaution against drought, and to take advantage of the high prices that ruled every four or five years. A good discussion followed.

**TWO WELLS, April 27th.**—**WHEAT-GROWING.**—Mr. G. M. Cordon said the first essential was a good seed bed. He gave some practical hints regarding drilling, and said that if the land was very dirty the disc drill was the most suitable implement to use. To kill weeds on loose sandy land it was advisable to cross-harrow after the drill, and repeat the operation three days or four days later. He also advocated the rolling of the young crop, and, in good seasons, the feeding off of the early growth with sheep. In the discussion that followed the Chairman said the grain sown this season would be better placed fairly deep, as moisture had percolated well down into the soil. Messrs. Frost and Oke also contributed to the criticism.

## YORKE PENINSULA DISTRICT.

### (TO BUTE.)

**BUTE** (Average annual rainfall, 15.42in.).

**February 23rd.**—Present: 20 members and one visitor.

**POULTRY BREEDING AND RAISING.**—Mr. A. E. Bryant read the following paper:—"The first thing to study is the housing of the fowls. The fowlhouses should be built of galvanized iron, with as little wood as possible, and all on the outside so

as to prevent tick from getting into the houses and breeding. They should face the east, so that the fowls get the early morning sun; should be dry and warm, well ventilated, but on no account draughty. They should be cleaned out every week and disinfected, so as to prevent disease. A little fresh lime and sand put in the houses make a great improvement, and keep the places fresh. The water tins should be kept in the shade, as the fowls need plenty of fresh water during the warm weather. A little Epsom salts is a good thing to put in the water occasionally. The next thing to study is the best fowls to keep. For laying purposes only, I should recommend the White Leghorn. The other fowls I am very much in favor of are the Silver and White Wyandottes, White and Black Orpingtons, Faverolles, Rhode Island Reds, Red Sussex, and Plymouth Rocks. All these breeds are very good layers, good table birds, and also real good for cross breeding. The Wyandotte is a good table bird, and has great laying abilities. They are good sitters, but not so good as mothers, on account of their wanting to lay again when the brood is only four to six weeks old. The Orpington possesses greater length of body than the Wyandotte. It is this length of keel, and the depth and breadth of body, that give the Orpington its massive appearance. Anything that will take from it that character will hurt the breed more than it can possibly add in utility qualities. The Faverolle comes from France, a country noted for its high-class table birds. Although bred for table purposes, it has been found by expert poultry men to be a prolific layer, more especially in winter, of a medium-sized egg of a dark cream color. The progeny, too, are robust, quick in growth, and very fleshy, so that they make ideal market birds at a very early stage. The breed is very valuable to cross with. There are a great number of poultry keepers who have a strong liking for cross-bred fowls, and under certain conditions first crosses are almost, if not equal, to pure bred birds, but such crosses must be judiciously selected. For eggs alone I should recommend the following first crosses:—Minorca and Orpington, Minorca and Wyandotte, Minorca and Plymouth Rock, Leghorn and Houdan, and Leghorn and Red Sussex. All these make excellent all-round layers of good-sized eggs. They do not become broody too often, and when they do they are easily checked of their desire to sit. They are hardy, and can withstand the cold wet weather, though, of course, all reasonable care must be taken of them. For spring chickens the following crosses are everything that can be desired:—Faverolles and Red Sussex, Faverolles and Orpingtons, Faverolles and Dorkings, Houdan and Orpingtons, Houdan and Dorkings, and Red Sussex and Orpingtons. For table bird alone, I should recommend Indian Game with the following breeds:—Red Sussex, Dorkings, and Orpingtons. The Old English Game cockerel may be used in place of the Indian Game if so wished. When crossing the cockerel used should be the lighter breed of the two. Thus when mating a pen of Leghorns and Orpingtons, use the Leghorn cockerel and Orpington hen. If mated the other way, not only are the results less satisfactory, but much injury may be caused by the cockerel being far too heavy. On no account whatever use a cross-bred cockerel, as no good can come of such a mating. Second crosses are to be obtained by running a pure bred cockerel with first cross hens."

BUTE (Average annual rainfall, 15.42in.).

March 30th.—Present: 19 members.

SHOULD FARMERS CO-OPERATE?—This question was introduced by Mr. S. Tren-grove, who said the producers, being the backbone of the country, should be organized, and that the management of the country should be in their hands. By organization he did not mean paying half a guinea to join a society, and then, considering duty done, dropping into a deep sleep. It was not sufficient for the men on the land to simply produce and let others dispose of the products at their own sweet will. He referred to the influence exerted by the S.A. Farmers' Co-operative Union in hardening the price of wheat. With 6,000 shareholders to support it, the society had entered into the wool business. He claimed the right for producers to co-operate. Farmers were not as patriotic as they should be, judging by the large quantities of imported machinery used on the farms. Agricultural machinery, equal to the imported, could be manufactured locally. Many hands would be employed, and much-needed capital would not be sent out of the country. The same remark applied to superphosphates. A close co-operation between masters and men was required, as what hit the employer affected the

interests of the men. Farmers were compelled to co-operate to defend their interests. If they were unjustly treated by any particular business they had sufficient capital collectively to paddle their own canoe. They should be independent of the Government, except in times of great national trial like the present.

**YORKETOWN, April 17th.**—Members decided that there was nothing to be gained by attempting co-operation in the purchase of machinery. Methods of pickling wheat were reviewed. Pickling on the floor with a bluestone solution or in a large shallow box, were the modes favored. Some members thought that washing the wheat grains would help to get rid of smut balls. Thorough stirring, in order to get every grain properly wetted, was more important than the use of a strong solution. One pound of bluestone to 10galls. of water was sufficient if well mixed.

## WESTERN DISTRICT.

### CARROW.

**April 29th.**—Present: 12 members and one visitor.

**HAWKS AND FOXES.**—Mr. J. T. Beare said he thought sheep and poultry were the most profitable side lines, but he had experienced much trouble with foxes and hawks. Mr. C. G. Anear thought the best way to get rid of hawks was to pay 2s. per head scalp money. The Secretary (Mr. T. Burt) said the simplest way to destroy foxes was as follows:—"Make a trail where foxes frequent, and drag some sheep entrails along it. Obtain a few sparrows, and slit open their breasts with a pocket knife to insert a little strychnine. Tongs made of hoop iron should be used to handle the sparrows, which on no account should be allowed to touch the person. The baits should be carried in a billy-can, and distributed with a piece of wire or stick, or with tongs." The Chairman said he found sheep difficult to manage, on account of the water shortage, and the fact that feed was not regular in new country. They would pay better when good summer grasses or lucerne were grown.

**ELBOW HILL (Average annual rainfall, 11in. to 12in.).**

**January 31st.**—Present: 10 members and three visitors.

**SEEDING AND WHEAT VARIETIES.**—The Secretary (Mr. G. F. Walke) referred to these subjects. He recommended Marshall's No. 3 and German Wonder as the best wheats for early sowing. Land worked when wet the previous season had given fair returns, but that treated when dry proved an absolute failure. Mr. S. Walke had obtained best results with Golden Drop. Shallow ploughing had given the best returns. Mr. W. Nicholas found wet working the best. Mr. P. Wheeler said his stubble land sown when the soil was wet, beat the fallow that was sown dry. Mr. F. Chilman had secured equal returns from stubble and fallow. Mr. A. Chibnan secured a 5-bush. average from early sowing, and much less from later crops sown under dry conditions. A wheat named Dissolution had been his best yielder. Mr. P. Wake had got the best results from seed procured from another locality.

**ELBOW HILL (Average annual rainfall, 11in. to 12in.).**

**April 24th.**—Present: 10 members and three visitors.

**PROVISION FOR LEAN YEARS.**—Lessons of the drought were emphasized by Mr. J. Wake, who praised the virtues of cocky chaff, and advocated the co-operative use of motor winnowers by neighboring farmers in conserving it in good years as a stand-by in time of need. During the capital seasons, he said, farmers got into the way of just cutting enough hay to carry their stock through the harvest and seeding operations. They neglected to provide for a year when there was no hay to cut. He advocated the use of the stripper and the motor winnower in preference to the harvester, and the saving of the cocky chaff. He also recommended the farmers to stack their straw, and, if possible, to cut a portion of their crop for heading purposes. Headed straw around Kadina had realised £8 per ton, so that the amount of the waste in the past could be better imagined than computed. Mr. H. Wheeler said cocky chaff could be stored for years without deteriorating. Mr. T. Spence considered headed straw preferable to cocky chaff, and Mr. P. Wake

advocated co-operation in the use of the motor winnower. Mr. A. Chilman said co-operation was difficult, as each farmer would want their wheat cleaned at the same time. Mr. F. Freeth described the advantages of the silo. Mr. F. Freeth read a paper from *The Journal* dealing with the value of white metalling. A profitable discussion followed.

#### GREEN PATCH (Average annual rainfall, 26.56in.).

April 26th.—Present: nine members.

PLANTING FRUIT TREES.—Mr. E. M. Sage read a paper on this subject. He said the first consideration was the situation. The best position in that district was a slope facing northerly from either east or west, with thorough protection from east to west on the southern side. Cold winds were more harmful than warm ones. The soil should have a light, quick-draining surface with a clay subsoil at least 9in. below. If so situated as to be easily freed from an over-supply of water in the winter, deep alluvial soil would suit admirably. Areas that had been cleared and cropped for some years were more suitable than new land. The soil should be ploughed as deeply as possible without bringing the subsoil to the surface, and should be deeply cultivated afterwards. It was a mistake to sink deep holes in the subsoil for planting, as they acted as tanks collecting water round the base of the tree. Holes large enough to allow plenty of room for the roots to be spread out, should be opened out to the depth of the ploughing. Roots should not be pruned except to cut away broken parts with the cut surface on the under side. He condemned the practice of planting on the surface and banking the soil up as if one or two dry summers were experienced before the trees were fully established they suffered before the roots got well down into the subsoil. His method was to lay a straight stick across the hole and keep the tree at least an inch higher than it was in the nursery bed, shaking fine soil amongst the roots, at the same time giving the tree a gentle shake up and down. The soil was then pressed firmly around the tree, and levelled up. The tree was pruned sharp back, either to a straight stem or to three or four arms about 4in. long. For many years the local market would be more profitable than the export trade, therefore the grower required a wide range of varieties covering sorts from the earliest to the latest. On suitable soil it would pay to specialise with peaches which commanded a ready market, and covered as long a season as any other kind of fruit. He had found peaches on peach stocks a failure in the district, and preferred them on almonds. In reply to questions Mr. Sage stated that the main roots of fruit trees did not go below the clay, but followed along the top of it. The apple and pear preferred shallow soils, with, say, the subsoil 9in. below the surface, but stone fruits would do much better in the deep alluvial soils.

#### KOONIBBA.

January 26th.—Present: 14 members and three visitors.

PICKLING WHEAT.—A short paper on this subject was read by Mr. A. Schmidt. The strength of the pickle to be used, he said, varied according to the variety of wheat, and the time of the year it was to be sown. Generally speaking 2oz. of bluestone to one gallon of water per bushel should be used, and a little fresh bluestone added to the solution after every two bags were pickled. Seed from wheat pickled the previous season needed practically no pickling, or a very weak one, if taken from a wet to a dry district, or from heavy to light land, or vice versa. If the seed was of a variety not much subjected to smut, only a weak pickling would be necessary. Seed sown late in the season after good rains was more susceptible to smut, and required careful pickling. Seed wheat should always be pickled at least one week before it was sown, and be perfectly dry. He deprecated the practice of sowing wheat that had been reaped before it was properly ripe. A lengthy discussion followed the reading of the paper. Mr. J. Foggo had had experience with different kinds of pickling solutions, and had come to the conclusion that the bluestone mixture was most effective. He also considered that manure mixed with the wheat and left for a day or two was a prevention against smut. Mr. E. Gersch thought that a bag of wheat placed in the pickle for three minutes would be thoroughly treated; but Mr. R. Schultz considered that this was not so. Messrs. Lutz, Foggo, and Lemme considered that a change of land was a preventive. The Hon. Sec. (Mr. R. Lemme), and Mr. H. Schroeder also contributed to the discussion. [Pickling wheat does not appreciably weaken the solution being used, therefore it is unwise to add bluestone, and thus strengthen the solution.—ED.]

## KOONIBBA.

April 27th.—Present: 12 members and two visitors.

**FARM IMPLEMENTS.**—Mr. E. E. Lutz concluded his paper on this subject. He described the ploughs used in the district, and said he thought a medium light seven-furrow the best size. He recommended the four-leaf stump-jumping harrows with wheels 15in. high, and tines 9in. high. The disc cultivator left the land uneven. The kind required was one with fairly high wheels to enable the frame to pass over stumps. The disc plough was useful for ploughing in stubble. A 9-furrow bridle draught implement was the best. The 15-disc drill was best suited to the requirements of the district. Binders were preferable to grasscutters, as hay was kept clean, and there was no waste. He also described the makes of strippers and harvesters in use, and urged members to take proper care of their implements and machinery. Members freely expressed their views on the comparative merits of the binder and the grasscutter. Messrs. A. R. Schultz, H. Schroeder, and Linke were of the opinion that hay cut with a side-delivery grasscutter produced better quality hay than the binder. Mr. Schultz said that during the past two or three years land sown for hay had not produced sufficient growth for cutting with the binder. With a side-delivery grasscutter he could mow in fields not clear of stumps. Some members preferred the binder, and Mr. Foggo said if a smaller cut machine was used it would be found an advantage.

## KOPPIO (Average annual rainfall, 22.40in.).

April 29th.—Present: nine members.

**CONSERVATION OF FODDER.**—Some practical advice was given by Mr. G. B. Gardner, who read a paper on this subject. He alluded to the vagaries of the weather during the past two seasons, and as much of the rain recorded fell when it was of no direct benefit to the cereal crops, he argued that summer crops could often be cultivated successfully. Although lucerne was generally understood to require irrigation it could be grown on selected spots where artificial watering was impossible. One acre of such lucerne after a summer rain, was equal to 20 acres of dry grass for feeding purposes, and in the autumn it would give a lot of early feed before the ordinary grasses were available. He had fed down a plot of kale consistently for three years, and although it had been overstocked and eaten to the ground, it still provided valuable feed. The dry seasons taught them to conserve cocky chaff and straw. He believed in storing sufficient hay to supply 12 months' requirements. To obtain early feed he advocated dry sowing barley before the early rains.

**RABBIT DESTRUCTION.**—Mr. R. Schultze described his experiences. After seven years' trapping he found spring traps the best for winter work. To catch rabbits that burrowed under fences the best plan was to set the trap about 6in. to 8in. away from the fence. At the burrows the trap should be placed a few inches away from the holes. The traps should be skilfully masked. When skins were the objective the trapper should find the feeding grounds and make trenches 2ft. long, 4in. wide, and 4in. deep, on dunghills if possible. The trenches should be connected with a trail of broken earth. The traps should be bedded firmly one-third way up the trenches, the left jaw and part of the plate being covered with a piece of paper hidden by a thin layer of soil. The trap pegs should be 8in. to 10in. long, be made of strong fencing wire, and be driven out of sight in the soil. Traps should be cleared at sundown and again at 9 p.m. Two men could manage 100 traps and make good wages.

## SALT CREEK.

April 24th.—Present: 12 members and five visitors.

**DRENCHING A HORSE.**—Mr. T. C. Hornhardt read a paper describing the method of constructing a crush pen for this purpose. He said a cheap and handy contrivance could be readily erected as follows:—"Mark out a crush pen of sufficient dimensions to accommodate a large horse. Four strong posts are required for the corners; these should be placed in the ground to a depth of 3ft. The front posts should be of such a length that when a bar is secured across the top a rope may be thrown over and attached to the horse's bridle so that his head could be drawn up to the height required for giving the drench. Strong side rails, wired or bolted to the posts, complete the structure. When the horse to be treated is penned, a rope placed over its wither and tied to the side

rails will prevent it from rearing, while a strap placed on one of its front feet and secured to the bottom of a post will effectively stop the animal from striking. The drench may then be administered with confidence." He preferred using a lemonade bottle to a drenching bit. The Secretary favored taking the weight of the animal by means of belly-bands instead of tying the legs, as less injury resulted. Several members spoke in favor of the beat drenching bit, and others preferred the lemonade bottle.

#### ROBERTS AND VERRAN.

April 27th.—Present: eight members.

**ECONOMY IN FEEDING HORSES.**—A paper on this subject was read by Mr. W. Sharman. He said a man who was careful in feeding his horses would make a given quantity of feed go further and do more good. The capacity and requirements of each horse should be studied. The practice of putting enough feed in the manger at night to do for the morning meal also, was wasteful. A horse doing slow work could be kept in good condition by feeding with hay chaff alone, but the quantity could be reduced if grain, preferably crushed oats, was added. Cocky chaff alone was of little value, except to keep stock from starving, but with the addition of crushed corn, pollard, bran, or molasses, it made an admirable substitute for hay chaff. Horses in hard work should be well and regularly fed, and should be allowed 1½ hours spell at midday. They should be watered before being fed. Working horses should receive three good feeds per day, and another at about 9 p.m. As it was difficult to get a heavy cut of hay in the district it was advisable to sow a considerable area with oats and strip them for horse feed. Comfortable stabling during cold weather reduced the fodder bill. Dry sowing a paddock adjacent to the stables with early wheat or barley before the first rains, would produce early green feed on which horses could be turned at night. At harvest time the first paddock harvested should be handily situated so that it became available for horses at night or stock not in work. To keep the horses in health, a bran mash made by pouring boiling water on about 3lbs. of bran and allowing it to cool under a bag, should be given on Saturday nights. A handful of salt should be mixed in the bran. Rock salt should always be kept in the manger. Mr. F. Masters agreed with the writer, but considered that under present circumstances the advice would be hard to follow in detail. Mr. A. T. Cowley thought cocky chaff and bran a useful food, and favored giving bran mashes once a week. Mr. P. Whittaker preferred feeding horses with long hay at night time. Mr. D. Hoar agreed with the points outlined in the paper.

#### YABMANA (Average annual rainfall, 15.14in.).

February 27th.—Present: 11 members and four visitors.

**AWAKENING INTEREST IN BUREAU MEETINGS.**—A motion, moved by Mr. M. Robertson, to the effect that every member in rotation should take part in each discussion, was carried unanimously. Mr. G. W. Story followed with a practical paper dealing with methods of making Bureau meetings more interesting. He urged upon members the necessity for regular attendance and punctuality. Observance of these matters was imperative, as it was not only courteous to the Chairman and the Secretary, but helped to make the meeting go with a good swing from the beginning. The writer succinctly stated the rules of debate for the benefit of members. Mr. J. F. Robertson said irregular attendance of members was a thing to be avoided, but precise punctuality on the part of the Chairman and the Secretary would set an example worthy of emulation. The system of asking every member in turn to discuss subjects had proved effective in adding interest to the meetings of the Coomooroo Branch. Mr. K. Frost said that sometimes a member whose turn it was to write a paper found it convenient to be absent. Messrs. S. G. Strother, J. Y. Robertson, G. Dorey, and A. Beinke also spoke. The Chairman said that he had no reason to complain of the attendances at the meetings, as the recent visit of the Director of Agriculture (Prof. Perkins) and the Secretary of the Advisory Board (Mr. G. G. Nicholls) had induced a greater activity among members.

#### YADNARIE (Average annual rainfall, 14.09in.).

April 3rd.—Present: 18 members and eight visitors.

**SOWING SEED.**—Mr. E. E. Stubing read a paper on this subject. He said that the amount of seed sown per acre varied with different conditions, such as the

variety of grain, the tilth and freedom of the soil from weeds, and the rainfall. He considered that 45lbs. of seed of a late variety, and from 50lbs. to 55lbs. of an early variety per acre was ample, if sown early. When sowing in. was deep enough to bury the seed, as otherwise it would only re-root at its natural depth. To secure a good seed bed the harrow was the best implement. Land which had been fallowed should be harrowed before drilling, and land which had been cultivated should be harrowed after drilling. Care should be taken in pickling wheat that had been wet previous to harvesting, as it required different treatment from wheat gathered dry. A good discussion followed, and members generally favored sowing deeper than that advocated by the writer.

**SEED AND MANURE TEST.**—Mr. S. H. Pearce submitted results of experiments that he had conducted.

#### YEELANNA.

May 1st.—Present: 12 members.

**KALE.**—Mr. J. Dunn tabled a fine specimen of "King" kale, 4ft. in height and 9ft. in circumference. The seed was sown in August, on light sandy soil, to which a little superphosphate was applied.

**SEEDING IN 1915.**—This subject was dealt with by Mr. J. J. Cronin, who said every farmer should endeavor to sow as large an acreage with wheat as possible, to help meet the world's demand for food, and to secure the satisfactory prices that were certain. He advocated sowing stubble land, as on account of the abnormal conditions the previous seasons, it was likely to produce fair crops without the application of much manure. For fallow land on which the crop had been cut for hay, he advised cultivation with some light implement, and then drilling in wheat at the rate of 45lbs. to the acre, with from 45lbs. to 60lbs. of super. A second crop would enable the farmer to secure a stubble burn before the next seeding. They all knew the benefits of a systematic fire-raking on a mallee farm. He recommended harrowing a month or so after the crop had sprung, as in these seasons every ounce of moisture that could be retained in the soil was required. A discussion followed. Members agreed with the remarks of the writer. Messrs. J. Carey and A. E. Skipworth considered that harrowing the growing crop was beneficial.

**KOONIBEA, March 30th.**—**FARM IMPLEMENTS.**—Following on a paper read by Mr. Lutz, there was a general discussion upon the merits of spring versus bridle draught. Messrs. Lutz, R. Schultz, and H. Schroeder favored the bridle draught. Mr. B. Koch advocated the latest style of spring draught, which, he said, rendered it impossible for the shares to hang up in the stumps. The suggestion of a visitor that a field trial should be held in the near future was approved. Members considered 4-leaf harrows were large enough for use in the district. Various makes of drills were criticised. Mr. Schultz urged members to be satisfied with a 13-disc drill, as the 15-disc machine only covered two acres more per day and required an extra horse in the team.

**MILTALIE, April 22nd.**—**FEEDING FARM STOCK.**—A paper on this subject was read by the Chairman (Mr. T. A. Wilson), who described how some improvements could be effected. The aim should be to get the best food at a minimum cost. He advocated a balanced ration. Messrs. L. Auger and J. S. Jacobs contributed to a profitable discussion.

**YABMANA, April 29th.**—**CO-OPERATION.**—Members discussed the co-operative proposals regarding the purchase of farm requisites made by the Clare Branch, and decided not to support them. Mr. G. W. Story read a lengthy paper on co-operation, in which he described the objects and advantages of the S.A. Farmers' Co-operative Union.

**YADNARIE, April 24th.**—A paper on "Co-operation" submitted by the Clare Branch at the 1914 congress, was read by Mr. Johnson. The majority of members did not favor the system outlined, but opined that the Co-operative Farmers' Union deserved their best attention. Mr. A. A. Jericho thought the movement of the Clare Branch should be encouraged. Mr. B. B. Crosby believed in the co-operative purchase of manure and implements, providing the terms were equal to those offered by independent firms. Messrs. S. H. Pearce, A. Spriggs, F. W. Dreikow, and E. C. Stirling also took part in the discussion that followed. A paper on "Harness Troubles" was read by Mr. B. B. Crosby, and was reserved for criticism at the next meeting.

**EASTERN DISTRICT.****(EAST OF MOUNT LOFTY RANGES.)****BOOKPURNONG EAST.**

March 27th.—Present: 13 members and two visitors.

**SEEDING PREPARATIONS.**—Mr. E. E. Vogelsang advised members to thoroughly overhaul their machinery before the eleventh hour. A little timely attention and adjustment before the machines were needed saved much valuable time. Seed wheat should be put through the winnower a second time, or, if possible, graded. More seed and a heavier application of super. was necessary on sandy rises than on the flats. The crop was given a chance to grow quickly and thickly, thus minimising the risk of damage from drift sand. Opinions varied in the discussion that followed as to the desirable amount of seed and super. necessary for each acre. The average requirement was estimated at about 50lbs. of seed and 45lbs. of super.

**BORRIKA.**

March 27th.—Present: 21 members and three visitors.

**ROTATION AND SUBDIVISION.**—This subject was dealt with by Mr. A. E. Seary, who referred particularly to the mallee country. He described the two-year rotation system (bare fallow, wheat); and the three-year method (bare fallow, wheat, grazing). The two-year system, he said, was suitable for holdings of not more than 500 acres, two main subdivisions of the farm only being required. For an average holding of 1,000 acres the three-year system meant that about 300 acres were in crop each year, with a minimum of 300 acres always out for feed, while weeds on a similar area of fallow were also available. Three main subdivisions would be required at least. The system of cropping with wheat every fourth year was gradually coming into favor in the mallee districts of Victoria and South Australia. It was more suitable than the three-year rotation on large farms, where much stock was carried. The land would be utilised:—From July to the following April, bare fallow; May to January, under wheat; January to March, stubble grazing; cultivate in March, dry if necessary, and sow with oats for grain and hay, and also with barley as a feed-off crop; January to the following July, grazing; July to April, bare fallow; and then crop again with wheat. A division of the farm into four paddocks was necessary. The systems could be modified as required. Subdivisions should be so arranged that stock could go in for water from each paddock without special attention. A discussion followed. Mr. E. H. Huxtable thought that two successive crops were best in new mallee country, where shoots and scrub growth had to be contended with. Mr. G. Miell preferred sowing oats and barley as a follow-on crop instead of fallowing, which facilitated drift. Mr. Brown favored sowing oats and burning the stubble to kill shoots. Messrs. Jones, Green, Gray, and Hart also gave their opinions.

**BORRIKA.**

April 24th.—Present: 21 members and five visitors.

**SEEDING.**—A paper on this subject was contributed by Mr. G. Stephen, who advocated starting the drill in the first week of April if the soil was dry, or wet enough to ensure germination. He applied 40lbs. and 50lbs. of super. on new land and stubble land respectively. When sowing early he used 45lbs. of seed, and for later planting 1bush. to the acre, especially in a wet season. He pickled with bluestone one month before sowing the seed. It was advisable to plough all land early, to give time to pick up stumps. He ploughed old land 3in. deep where sandy, and 3½in. where firmer. New ground was ploughed shallow. He preferred drilling deep for early sowing, and shallow for late planting. Harrowing after the drill helped to retain moisture. He preferred harrowing to rolling on sandy soil, as there was less likelihood of drift. The best time to cut shoots was in March and April. Rolling the scrub one year and burning it off in the next, after the shoots had been cut, helped to kill the stumps. Mr. G. Miell said shrivelled wheat would grow all right if the soil was moist. Messrs. Gray, E. H. Huxtable, J. B. Tonkin, and Bowden also contributed to the discussion.

**BRINKLEY.**

May 1st.—Present: nine members.

**BINDER TWINE IN CHAFF.**—It was decided to bring under the notice of the September congress the injurious practice of chaff merchants in cutting up binder string when chaffing hay. Members complained that the twine collected in balls in the horses' stomachs and caused serious trouble.

**MALTING OF WHEAT.**—Mr. H. D. Humphrey said that he had found that there was no danger of wheat sown dry malting in that district. On sandy patches the seed might spring with the moisture, but on hard land it would lie for weeks till a good rain fell. In most cases not more than 10 to 15 per cent. would malt, and when a bushel of seed was sown to the acre, the resulting growth would be quite thick enough. Mr. E. Schenscher stated that two years ago his seed, sown early and dry, germinated after light rain, and one-half of the plants died back. He favored waiting for a good rain before sowing. Oats were not likely to malt.

**COOMANDOOK (Average annual rainfall, 18.01in.).**

February 27th.—Present: 25 members.

**HAY-GROWING.**—Mr. L. A. Williams, in a paper dealing with this subject, said that for hay-growing he favored soil of red loam, or failing that, ground of half heavy land and half sandy loam. The ground should first be ploughed in July with a 4-furrow plough to a depth of 3½in., harrowed, and then allowed to lie idle until September. It should then be worked with a skim plough or tine cultivator, and harrowed again. Harrowing could not be done too often, especially after rains. In the middle of April, after further ploughing to a depth of 1½in., the land should be sown with 70lbs. of super. to a bushel of Calcutta oats, as they came in early, and consequently haycarting could be completed before stripping commenced. After drilling it should again be harrowed in order to bury any seed left uncovered. He preferred the binder to the mower for cutting hay, which should be placed in stooks of from 20 to 25 sheaves and so protected from the rain. After about eight days it should be stacked and left about a week, before chaffing. Mr. O. Blucher also read a paper on this subject, agreeing very largely with the previous one. He said that for wheaten hay 50lbs. wheat to the acre with 112lbs. super. should be sown, and for oaten hay 40lbs. to the acre, with the same quantity of super. For wheaten hay he favored White Tuscan, Dart's, Baroota Wonder, and Vandilla King; and for oaten hay Algerian and Calcutta Cape. Algerian oats should not be cut before showing a yellow tinge, while wheat should be cut about a week after the flowers had dropped off. When stacking it was best to have the centre of the stack about 18in. higher than the outside, and a little salt should be sprinkled on each layer. The stack should be about a foot wider at the top than at the bottom, and should have a good steep roof to protect it against thunderstorms before being covered. When the hay was chaffed it should be damped at least 12 hours before cutting, with just enough water to toughen it.

**GOVERNMENT AID TO FARMERS.**—Mr. H. Marsh read a paper on this question, referring particularly to the handling, storing, and marketing of wheat. He said that farmers in that district had to accept 3s. 3d. a bushel for wheat, when the price at Port Adelaide was 3s. 8d., the difference being made up by railway charges and merchants' profits. He contended that farmers should be able to sell direct to the shipper, and that this might be brought about by the establishment by the Government of Farmers' Associations in each township, and the erection of suitable sheds for storing the wheat. Each farmer could have a space in these sheds allotted to him, where he could place his wheat, and brand it with his particular mark. Provision should be made in the scheme for obtaining an advance on the wheat while it was being held for prospective higher values. He further argued that by selling in big parcels direct to the shipper a further saving would be made by the farmer. An advance of 1½d. or 2d. a bushel could be obtained on big parcels in comparison to farmers' lots. He added, in conclusion, that the storage sheds could be used for other products besides wheat, such as super., cornsacks, &c.

**FORSTER (Average annual rainfall, 10in. to 11in.).**

April 24th.—Present: six members.

**HORSES AND FODDER.**—These subjects were referred to by Mr. E. Towill, who said that "the farmer who looks after his horses looks after himself." He ad-

vised producers when harvesting to cut at least a 12-months' supply of hay for his stock. Fallow land in nine years out of 10 would produce twice the amount of wheat that could be grown on other land. Therefore it paid to conserve fodder for the horses, so that more land could be fallowed than would otherwise be the case. He deprecated the "feast and famine" system, under which in good seasons stock were allowed more fodder than necessary and in droughty times were half-starved. Often horses were fed in the stable when there was an ample supply of herbage available in the paddocks. Mr. W. Searle believed in mixing headed straw with oaten hay. Messrs. T. and J. Searle also contributed to the discussion.

GLENCOPE (Average annual rainfall, 10.07in.).

December 28th.—Present: eight members.

LIMING LAND.—A paper dealing with this subject was read by Mr. M. J. Walsh, who described the effects of lime on various soils. To determine whether soil was deficient in lime, he recommended the following test:—"Take a few shovelfuls of soil from different parts of the paddock, and when dry, pulverise it finely. Take a few ounces of this mixture and reduce it to ashes on a shovel placed over a fire. When the ashes are cool place them in a tumbler with sufficient rain water to cover them. Stir with a glass rod or wooden stick, and add 1oz. of hydrochloric acid. Stir again, and if a brisk effervescence occurs the percentage of lime is fair; if little or no effervescence takes place the soil contains little or no lime." Mr. H. S. Cope stated that he had carried out liming experiments in Victoria over a series of years, and had obtained some extraordinary results. In that district the heavier soils of all the flats required a heavy dressing of lime, because they contained a high percentage of mineral acids. He recommended giving a dressing of half a ton to the acre every third year. The lime should be broken small, spread over the land in the following season, and ploughed in the same day. Treated in this way land would produce heavier crops with half the quantity of super. necessary on similar land unlimed. Messrs. C. A. Evans, J. F. Colbert, and F. Braselmann also believed that liming was necessary.

MANTUNG.

April 1st.—Present: eight members and four visitors.

COWS FOR THE FARM.—Mr. E. Hannaford said the dual-purpose cow met the requirements of landholders in the district. The milking Durham was not suitable for them on account of the large quantities of feed required by such large-framed beasts. They wanted a class that would return a substantial butter supply as well as be saleable for meat purposes. The Jersey, with its high butter production, suited the dairyman, but it was too small for local requirements. A cross between the Shorthorn and the Jersey was in most cases suitable for local breeders. With medium-sized cattle, milked regularly, and fed well, cows were a profitable proposition if in-breeding was guarded against. Mr. A. Tonkin preferred the Durham to the Jersey for farm use. Mr. A. Hannaford considered that there was a tendency in the markets towards preference for smaller cattle for beef. Any cross with the Alderney would produce a good butter cow. Mr. W. Eddy said the Durham-Hereford cross produced the best beef. Mr. G. N. Baker liked the small-framed cow, giving rich milk, for general use. Mr. J. E. Pearce said careful feeding was as essential as careful breeding. Mr. D. Stewart voted for the Jersey as the richest milker.

MANTUNG.

May 6th.—Present: seven members and one visitor.

SEED WHEAT.—Mr. A. Tonkin read a short paper on this subject. He said the seed wheat should be selected from varieties that succeeded best in the district. "Strangers" and barley should be pulled from the plot reserved for seed wheat purposes. To prevent smut he dipped half-bags of wheat into a cask of blue-stone solution, and allowed them to soak for a minute before turning them upside down to drain. He favored light sowing, about 45lbs. per acre, as a thin crop stood and withstood dry spells better than a thick one. Gluyas, Golden Drop, and Federation were very good wheats for the district. Mr. D. Stewart said he would grade all seed and sow heavier than 45lbs. per acre. Messrs. L. J. Pearce and H. W. Lehmann also spoke.

## MYPOLONGA.

April 27th.—Present: 19 members and 16 visitors.

LAYING OUT AN ORCHARD.—Mr. J. McKerlie (late of Moutaoute), said the first thing was to find out what kind of fruit trees were suited to the conditions of the soil. Trees should be obtained from the nearest source of supply. They should be planted to the depth they were raised in the nursery, and should be set out in rows so that from whichever angle they were looked at they were in line. Bruised or ragged ends of roots should be cleanly cut off with a knife, and the roots should be spread out in the hole. In reply to questions Mr. McKerlie said the trees should be planted 20ft. apart. The peach and apricot were the most profitable stone fruits on irrigated lands. Orange trees would be profitable. Walnuts would pay as windbreaks. Messrs. Wright, Rainer, Colles, and Hill contributed to the discussion.

## NETHERTON.

April 24th.—Present: 13 members.

IMPROVING THE FARM.—A paper dealing with this subject was read by Mr. Ritchie, who said that all buildings in that district should be constructed of stone. All buildings should be square on with each other. The stable and chaffhouse should be built together, with a partition wall along the middle, 6ft. higher than the sides, to form a gable. Half of the building would be used as a chaffhouse. The other portion, fitted with a race and a manger, would make the stable. Access to the race would be gained by a door fitted in the centre of the manger. The barn should be placed well away from the stable. A useful size was 40ft. by 20ft. He would have the floor raised 3ft. from the ground, so that the truck could be used to save a lot of labor in lifting. The building should have a 6-ft. gable and two faulights in the roof, one on each side, to allow of the admission of sunlight and air. Gateways in the farm paddocks should be 16ft. wide with two 8-ft. gates, to allow of a 7-horse team to be driven through without uncoupling or removing swings. Sugar gums or other trees should be planted to add to the æsthetic appearance of the homestead, and to provide breakwinds and shelter for stock. Members generally approved of the suggestions.

METHOD.—Some suggestions were made by Messrs. T. Datson and H. Gosden. They said farmers as a rule did too much guesswork, and thus made their work more laborious. Convenient arrangement of the farm buildings and stables was advocated. Stalls 6ft. wide were suggested for each horse. The addition occasionally of Epsom salts and Fowler's solution of arsenic in bran to the feed was recommended in order to keep the horses' blood healthy. Paddocks should be laid out to give the greatest convenience for working, harvesting, or handling stock. Thorough inspection of machinery before using, and cleaning and storage after use, was necessary. Members generally favored stalling the horses separately till after their last feed at night. Epsom salts and oats was considered sufficient medicine for horses on dry feed.

## PARILLA (Average annual rainfall, 16in. to 17in.).

April 15th.—Present: 15 members.

SHEEP ON THE FARM.—Mr. J. J. Foale alluded to the benefits derived by keeping some sheep on farms in the newer mallee hundreds. Conditions, however, he said, were not generally favorable in that district, owing to the lack of sheep-proof fences. Wire netting was required for boundary fences, as when properly erected it was both sheep and rabbit proof. Six-wire fences were sheep-proof for Merinos. During the past season, marked by the scantiness of herbage, his flock lived on the stubble, and, when lambing started, upon weeds. They thrived when turned on a heavy patch of charcoal. Subsequently they were placed on oats, drilled without manure on wheat stubble, which had previously been fed off by horses and cattle. The lambing result was over 100 per cent., and the average return per ewe worked out at 16s. 2d. When sheep were kept on the farm there was no need to be afraid of weeds. There was a profitable discussion, in which Messrs. J. Tee, G. E. Gregory, A. J. Stevens, C. E. Moyle, J. Northey, C. S. Foale, P. W. Lavis, H. G. J. Masters, M. Rush, C. B. Davies, and P. J. Barne participated.

**RAMCO.**

March 29th.—Present: six members and one visitor.

**SULPHURED SULTANAS.**—Mr. J. Parkes asked if members considered the samples tabled at the previous meeting were as good as dipped fruit? Mr. W. J. Green said the color was good, but the fruit was useless, being only skin, with no flesh, and too sharp in flavor.

**BEES.**—Mr. R. Stanley gave some practical advice to beekeepers. He described the life and habits of bees. Referring to diseases, he said foul brood was the worst. To cure it he recommended the destruction of the queen and the boxing of the hive into a common box, in which a new queen should be raised in the corner. Transference to a new hive, with a new queen and new comb, would complete the remedial measures. In reply to questions, Mr. Stanley said that the most honey he had ever taken from one hive in one season was nine tins, but an average of three tins was capital.

**RAMCO.**

April 26th.—Present: seven members and one visitor.

**SUGGESTIONS OF A NEWCOMER.**—Mr. R. Burnell thanked members for the assistance they had given him during his first year on the river. He said the first thing he noted upon his arrival at Ramco was the absence of flower gardens. They owed it to their womenfolk to make the surroundings of the home as beautiful as possible. He commented upon the small attention paid to the production of vegetables, and said that in the space occupied by four trees sufficient fresh produce could be grown for the home. The past dry season had shown that the man on the land did not keep enough fodder supplies on hand, and although lucerne was grown in the summer, there were few of them with a sufficiency to meet their full requirements. He suggested that the present season was a suitable time to lay in a stock of hay as the nucleus of a fodder reserve. He reminded members that no stock was good enough but the best. It paid better to feed one good heavy milking cow properly than to keep four inferior animals on short rations. It was cheaper to shoot their old worn-out horses than to feed them. They should be replaced with animals that would do all the work required. Sufficient attention was not paid to the running of fowls in the orchards. He advised each two or three neighbors to co-operate in the purchase of an incubator. He had noticed that sandy approaches to the houses of settlers had not been metalled. A few loads of gravel would make a vast improvement. The speaker concluded with some suggestions regarding water storage. A discussion followed. Mr. W. J. Green said difficulty in keeping flower and vegetable gardens going was created by the prevalence of hot winds in summer and the long time between irrigations. Mr. J. Parkes considered it difficult to keep fowls in the orchard, and that mice would spoil hay stored for two years. Mr. R. Stanley advocated chaffing the hay and storing it in a barn. Mr. T. Lewis said fowls were a nuisance in the grape season. He would raise them after the picking season and market them before the next crop ripened. Members then decided to offer two prizes for the best children's gardens, open to the scholars of the local school.

**SULPHURED SULTANAS.**—Mr. Rogers tabled some samples, which had been treated as follows:—Dipped in solution of 1lb. caustic soda to 22galls. water; allowed to stand on trays until slightly dry, then sulphured for about four hours. The quantity of sulphur used was 2½lbs. to 52 trays, 6ft. by 2ft. 6in. Members decided to experiment in this method next season.

**RENMARK (Average annual rainfall, 10.93in.).**

January 7th.—Present: nine members and two visitors.

**DRYING OF GRAPE FRUITS.**—Mr. W. E. Muspratt read the following paper on this subject:—"There is no doubt that the sun-dried fruit of the irrigation settlements is equal to anything put on to the markets of the world. But there is still a lot for us to learn so far as the actual drying is concerned, more especially as to labor-saving devices. The old 3ft. x 2ft. wooden tray, and the 6ft. x 3ft. tray have given place to the 4ft. x 3ft. tray, which has given satisfaction, and in many cases settlers have converted their old trays into this size. They save time in spreading, and having a cleat all round, stop loose berries from falling off. They also hold nearly as much fruit as three of the old trays."

They also fit under the 4ft. netting racks, their one drawback being that they are apt to hold the rain badly. The best racks are made with 4ft. netting, 2in. mesh, and 16 gauge or 17 gauge; bays 10ft., bottom netting at least 1ft. above ground, with three higher tiers 16in. or 18in. apart. These racks should run north and south, more especially for dipped fruit, so as to catch the maximum of sun. The earlier racks were built to carry canvas covers, and while these may not cost quite so much as corrugated iron on the first outlay, they soon perish. I have two racks with corrugated iron covers, under which I have dried successfully currants, sultanas, malagas, and gordos. The best size wire-netting tray is 8ft. x 4ft. 3in. This is made of 3in. x 2in. ends, 2in. x 2in. sides, 2in. x 1in. centre batten, with 17 gauge netting, 2in. mesh. Bind the corners with hoop iron, staple the netting on the ends, pulling fairly tight, and the netting will stretch the extra width easily. To get the necessary air space the best plan is to have uprights of sawn timber sunk into the ground as for racks, with 8ft. 1in. bays, and 2in. x 2in. cross pieces nailed on 8in. or 9in. apart, so as to form a slide to push the tray on. The uprights can be left any length to take whatever cover is required. This method lends itself to all vine fruits. Currants require the whole of the slats, sultanas and gordos every alternate one. For picking I prefer secateurs to knives. Give each man a chaff sack, with a couple of sticks or wire stitched in the long sides, to place on the ground under the spot being picked, so as to catch loose berries. When shifting past posts, &c., hold both sticks and run the berries into a box. Have all leaves picked out, and too solid bunches cut up as picked. If weeds are thick the chaff bag will be found of no value. I much prefer the wire basket to tins when dipping. As regards the strength of dip, there has been a tendency to go stronger with cooler temperature. This makes little difference on wooden trays placed straight out in a good sun, but on racks or netting trays it tends to darken the lower end of all berries hanging through the netting. For sultanas 16 to one is strong enough for the dip with the water boiling; malagas, 14 to 1; gordos, 10 to 1 to 12 to 1. The class of soil makes some difference, and so does the rack. The grower must watch and vary the dip when necessary. Ripe fruit takes a stronger dip than that on the green side, so a grower starting early would probably find 18 to 1 strong enough for a start, working up gradually to 16 to 1. It is best to renew the dip every day, as it may make the difference between three-crown and distillery fruit. Sultanas should be dipped as quickly as possible. A swing in and out is better than a straight plunge down, as fewer berries are liable to float out, and the hands do not suffer so much. Malagas require the same treatment as sultanas, and gordos about one second longer. The sooner fruit is spread after dipping the better. I use a tray made of 24-gauge iron (flat), 2ft. x 20in.; nail a 1in. wooden slat on both the 2ft. and 20in. edges, on the one face, and a slat 3in. in from the edge on the remaining end on the other face. The fruit should be laid on the bottom netting, starting at the left-hand corner, with the single slat side down, and to the left, and tipped on the tin and spread roughly, and the right hand side tilted and pulled to right, until the fruit is all off. The thickness of the fruit is regulated by the height of cant and sharpness of pull. It is better to have the berries spread thinly than too thickly. It is not possible to get so much fruit on, but the rack is released sooner for the next lot, and the small fly that appears when fruit is going off may not worry you. The fruit should be spread lightest on the bottom tier, getting thicker as the tiers rise. When making sideguards use old 3 x 2 matchboard trays. Saw through the cleats in the centre and nail together in lengths to suit the bays. On one side nail 1½in. x 1in. timber, to which attach legs, so that the foot-board stands at the angle of 45 degrees to the ground. These ground guards save a lot of fruit, both while spreading and scratching off. Cut hessian 2ft. longer than width of bays, and put in place with sideguards, and rub through two tiers. This will be found enough to carry away, also if the fruit from the two bottom tiers is kept separate from that on the top tiers it may make a crown difference, the latter being of a slightly better color. Netting trays are filled in the same way as the racks, except with currants, which can be put on straight out of the boxes. When emptying these trays lay hessian down and place four picking boxes on same, so that the tray corners rest on them. Turn the tray over and tap on the boxes. Very little fruit will be found to stick. Sweating is the best method of evening up nearly dried fruit.

When the hessian is pulled from under the racks it is in good condition to be spread out, but care must be taken to have the fruit spread the same thickness all over. It is better to leave the boxing up until the morning, but always roll up the hessians when cool. If done whilst hot, the fruit will sweat very much and get sticky, which takes getting rid of, even after the fruit is otherwise quite dry. All rack drying is in a measure shade drying, but on trays the fruit is in some cases left until quite dry and ready for boxing up. This is when the weevil gets its chance. All fruit is better for at least half a day's sun before boxing. Well filled but not rammed boxes should run from 14 to 16 to the ton. Three things may cause them to run over this, all of which can be overcome:—(1) Fruit too dry; (2) fruit picked too green, when it has little sugar; (3) want of manure, especially potash. Loose berries under racks should be shifted out into the sun as soon as each rack is filled, or with very long racks, say, twice a day, placing fresh trays to take their place under racks. Only leave enough fruit on each tray to cover it one deep. If put on thicker the berries take watching and turning to save them. It might pay to re-dip this fruit in hot water, without caustic. The berries are quite sticky to the touch, and always dry darker than the balance of same fruit that stays on the netting. To prevent the wind from blowing over stacks of trays, it is best to use a simple clip for the top trays. This can be made out of stout lin. hoop iron. Bend it into shape on a block of hardwood of the length necessary to clip two or three trays together, and turn about 2in. at each end, and use one of these clips on each side of the stack. A very useful implement for scraping fruit off the racks can be made out of a piece of fencing wire. I use a 6ft. length for mine, shaping it into a rough bow about 18in. long, and twisting the wire to make a stout handle." A good discussion followed the reading of the paper.

**SHERLOCK** (Average annual rainfall, 14in. to 15in.).

March 1st.—Present: 13 members and eight visitors.

**DAIRY HERD IMPROVEMENTS.**—The Chairman (Mr. A. G. Schneider) dealt with this subject. He said that even if they could not erect silos now they should aim at doing so later on. As 60 per cent. of the bulls in the State had disappeared, some by death, and others in the form of bully beef, it was to be hoped that they would be replaced by pure bred sires from recognised milking strains. His suggestion that later on the Branch might be instrumental in arranging to get a pedigree bull on the co-operative system for the members in the district, was well received. Members recognised the great importance of green feed, and favored lucerne, which was growing on several farms in the district without irrigation. One member stated that it was the lucerne on his farm that had enabled him to sell it at a good figure. Mr. Partridge asked about evening primrose, and it was decided to make further inquiries.

**POINTS TO REMEMBER.**—Attention was directed to the following information in the February issue of the *Journal*:—Death of mare through drench going the wrong way; the need to be careful that bluestone used for pickling was guaranteed 98 per cent. purity; that barley will stand more feeding off than oats; that new milk and honey were considered the safest cure for sand; that a plot of lucerne 12 yards square would be sufficient for 100 poultry; and that farmers should easily net £50 to £100 per annum out of poultry if properly managed.

**MALLEE STUMPS.**—It was admitted that until they were killed the best cropping results could not be obtained. The members agreed that new land would stand three successive crops, but that the land should be ploughed with a heavy tine plough until the mallee was dead. If this could not be done it would be better to leave it out and take time to fallow it properly. Stubble burns and sheep on the young shoots would greatly assist. The best time to cut shoots was from December to February, when the sap was up. A member said he was convinced that shoot slashers would soon be as antiquated as the reaping hook, and it would be a great day for the scrub farmer when some labor-saving method of dealing with the roots was invented. Members were unanimously in favor of mixed farming, sheep and dairying each having their champions. Mr. Smyth stated that he had no trouble with dingoes and foxes. He favored breeding lambs from a Shropshire ram and Merino ewes.

**SHERLOCK** (Average annual rainfall, 14in. to 15in.).

May 8th.—Present: 10 members and six visitors.

**SHEEP RAISING.**—A paper on this subject was forwarded by Mr. Smyth, and was read by the Chairman (Mr. A. G. Schneider). The writer stated that in the mallee country he considered the Merino was the best ewe to breed from, as it was quiet and required little fencing. He preferred mating with the Shropshire ram to produce strong, hardy lambs that were quick growers and fatteners. The best time for lambing was July and August, when the feed was at its best. An interesting discussion followed. The general opinion was that sheep would thrive and were profitable in themselves, besides being useful in clearing the land of weeds and young mallee shoots. Mr. A. Osborn suggested that goat raising might be profitable, but members generally preferred sheep.

**MISCELLANEOUS.**—Mr. T. Partridge said that the Director of Agriculture (Prof. Perkins) thought that "evening primrose" should be given a trial, particularly in sandy localities. Members decided to obtain some seed and report results. Several members signified their intention of starting wheat stud plots on the lines laid down by the Superintendent of Experimental Work (Mr. W. J. Spafford).

**WAIKERIE** (Average annual rainfall, 8.89in.).

March 26th.—Present: 29 members and three visitors.

**LUCERNE CULTIVATION.**—Mr. H. F. W. Lehmann contributed a paper on this subject. He said that in growing lucerne the first consideration was to secure level ground, and to see that the drainage was perfect. When ploughing, stable manure should be worked in, and the ground left with neither crown nor furrow. The ground should be well worked—harrowed and cultivated—and levelled to a fine tilth before sowing. From 8lbs. to 10lbs. of seed per acre was sufficient, and it should be sown broadcast or with a hand machine, in April or early September, with a light dressing of bone super. After sowing a brush bush or light plank should be dragged over the ground. Barley or oats sown with the lucerne in autumn secured a good cut of green feed and shielded the lucerne plants. It was necessary to cut at least a week before watering in order to give the plants time to start a fresh growth. The plant should be well in flower before cutting, and should then be raked and stooked. If it was cold weather it could remain in the stooks for a day or two, but should be carted much earlier in hot weather. It was better to cart too green than too dry. Stock should be fed with dry lucerne, as when green it tended to promote various complaints. He considered that Hunter River was the best variety. Arabian and Provence were good, but, having hollow stems, were not so weighty, although they grew faster and higher. The paper caused a good discussion.

**WILKAWATT** (Average annual rainfall, 16in. to 17in.).

April 24th.—Present: 10 members and one visitor.

**THE KITCHEN GARDEN.**—This subject was dealt with by Mr. W. R. Neville. He advised members when selecting a site to choose a good sand rise facing south, as it was protected from the blasting hot winds. He said it was an excellent plan to build a stump wall on the western and southern sides as a protection against the winter winds. A sand rise was better drained than heavier land, and would not show the effects of bore water so quickly. A manure pit was necessary, and could be cheaply and quickly constructed with four sheets of galvanized iron and a few iron posts. Manure required to be well rotted before being dug in. Old bags, if buried, became a valuable soil enricher when rotted. In reply to a question, Mr. Neville said rhubarb land required deep trenching, liberal manuring, and plenty of water in summer.

**HARROWS.**—A discussion was initiated on this subject. Members unanimously favored the slide on stump-jumping harrows in preference to wheels. One member stated that harrows pulled from the centre pulled a horse heavier than those pulled from each end by separate teams. A vote was taken, and one member favored the centre pull, nine plumping for the end pull.

**SOWING DRY.**—In reply to a question whether, considering the dryness of the soil, members would sow dry or pickled wheat, the majority favored sowing dry on dry land.

## WOODLEIGH.

March 31st.—Present: 11 members.

**FARM IMPLEMENTS AND WIDTH OF WAGONS.**—Mr. G. Vogelsang read a paper. He preferred a 10-furrow skim plough for working up stubble land after a good burn. For fallowing the 6-furrow was recommended. The 13-tine cultivator was useful in working up fallow land after rain. It was better than the disc cultivator, which, however, was very useful at times. A set of stump harrows was the best for the district, although the set harrows did better work in breaking clods and killing weeds. He preferred a 13 to 14 hoe drill, with the hoes not more than 7 in. apart. The disc drill was superior on rough rubbish-infested lands. The binder was indispensable, but on high sand ridges the 4 ft. 6 in. mower was a handy machine. He preferred the stripper to the harvester, as it saved the cocky chaff, which, this year, had been worth £6 per ton. He recommended a No. 4 chaff-cutter with horseworks. If there was work for an engine he would instal a 6-h.p. machine. A hand winnower was large enough for a small farmer. The trolly was easier to load than a wagon. The latter should carry four tons, and have 6 in. by 1 in. tires. All wagons and trollies in the district should be made one size, say with axles 5 ft. 6 in. in length. Carting would be facilitated, and the maintenance of roads would be less costly. Members generally agreed that the various implements and vehicles mentioned were the most suitable for the district. Mr. Maloney described the difficulties experienced from the cutting up of sandy roads by heavy carting with wagons of various widths. He said reform was necessary, but he failed to see how uniformity could be attained, as new settlers invariably brought with them wagons designed for use on metalled parts. The Chairman (Mr. E. T. Smith) said the regulation of the width of wagons was necessary. It was decided, on the motion of Mr. E. Good, seconded by Mr. F. Petch, that the Advisory Board of Agriculture be asked to consider the question, and if deemed advisable, to bring the present difficulty under the notice of the authorities.

## WYNARKA.

March 27th.—Present: 12 members.

**FARMING BURNT MALLEE LAND.**—Mr. A. Hood contributed a paper on this subject. When clearing burnt mallee land he advised using as heavy a roller as possible, as by that means more sticks and shoots were broken, and the land was easier to rake. It was best to roll the land in strips running north and south, as it facilitated the burn. He considered that by burning in February the best results were obtained. Ploughing should be done with a share plough with as little draught as possible to a depth of not more than 3 in. After fire-raking the stubble in January or February, the land should be ploughed again before sowing. He advised a rotation system of wheat, oats, grass, and then fallow. A good discussion followed.

**BERRI, April 28th.**—A paper dealing with the "Financial Aspect of Fruit-growing" was read by Mr. F. Arudt. He said that from the capitalists' standpoint stone fruits and saltanas did not work out too well, but citrus fruits returned a good profit on the money invested. A full discussion followed.

**CLAYPAN BORE, March 27th.—SEEDING.**—Mr. S. Gray read a paper dealing with methods of seeding. He said that land that was put under crop last season and failed to yield anything, would not require much working up before it was drilled. Some of the ground would only require from 40 lbs. to 50 lbs. of super., as there was still some left in the soil from the previous year. He considered that from 45 lbs. to 50 lbs. of seed to the acre was sufficient, as seed wheat was so dear.

**CLAYPAN BORE, April 26th.**—A visitor, Mr. E. G. Lee, read a paper on "Relations Between Employer and Employee." He treated the subject as an employee, who, after three years' experience, had become an employer. Messrs. Robinson, Hill, Colwill, and Dunstan spoke on the subject.

**HALIDON, April 28th.—WHEAT.**—The Secretary (Mr. W. F. D. Clark) described the history of wheat, and cited statisticians' figures regarding its production in the grain countries of the world. He compared the various methods of cultivation, and said that if it were not for the stripper 10 bush. crops would not

pay in Australia. He advocated the improvement of wheat by selection, and recommended everyone to read an article on the subject contributed to the *April Journal*, by the Superintendent of Experimental Work (Mr. W. J. Spafford). A full discussion followed.

**LAMEROO, April 5th.—BREAKING IN YOUNG HORSES.**—Mr. C. W. Davidson read a paper on this subject, which was well discussed. A young draught, he said, should be run round the yard a few times with only a halter on to which a strong rein was attached. The animal should be halted occasionally and patted. He should then be taught to lead. A strong rope, 24ft. long, should be used to take up all his legs until he would submit quietly to handling. In mouthing it was desirable to alternately fasten a rein to one side of the bit and tie it back to the tail. These performances should be repeated the second day, and then the colt should be tied up to a post for several hours. The third day the animal should be put into the shafts of the wagon, and tied down for safety. The fourth day the youngster would be ready for work in the team. He should only be worked half days for a time. His shoulders should be bathed with cold water to prevent sores. The preliminary training of the light horse was similar, but more time was required in mouthing, as he was usually ridden first. About the fourth day he should be saddled in the loose box, and for safety have one hind leg taken up with a rope just tight enough to prevent kicking. The colt should then be mounted, and dismounted on the wrong side, until he would stand. When the education had progressed thus far, the subject might be taken out on the fallow and ridden. After being ridden a few times he could be put into harness.

**LAMEROO, April 24th.**—The co-operative purchase of machinery was discussed, and it was decided at a future meeting to instruct delegates how to vote on the subject at the annual congress in September.

**LONG FLAT, April 26th.**—Mr. H. S. Mann gave notice that at the next meeting he would move—"That we request the Advisory Board of Agriculture to close the Branch in order that members may transfer to the Murray Bridge Branch."

**MINDARIE, March 15th.—CULTIVATION IN THE MALLEE.**—Mr. T. W. Kluge advised all mallee farmers to plough their land immediately after a burn, in order to conserve the potash contained in the ashes. As a preliminary he would plough a boundary break of 6 chains or 7 chains to arrest the drift of ashes. He recommended beginning cultivation about the second week in March, and drilling not later than the second week in April. Mr. Kluge quoted figures showing the relative cost of farming by contract and otherwise.

**MONARTO SOUTH, April 24th.**—The co-operative scheme promulgated by the Clare Branch was discussed, and a majority of those members present declared in its favor. Consideration was postponed till the next meeting, when a full attendance was expected.

**MONTEITH, April 30th.**—It was decided to call a special meeting to discuss the subject of co-operation.

**SHERLOCK, April 3rd.**—In a discussion on the most suitable wheats for the district members favored Marshall's for grain, and John Brown, Dart's Imperial, Western Wonder, and Huguenot for hay. The most favored pickle for seed wheat was 1lb. of bluestone to 10galls. of water. As a preventive of smut, the bags should be soaked in the solution beforehand. Treatment with a solution of  $\frac{1}{2}$ lb. of slaked lime in 10galls. of water was also recommended.

**WOLLOWA, April 29th.—INAUGURAL MEETING.**—The first meeting of the Branch was held at the residence of Messrs. Stone Bros., when the following foundation members were present:—Messrs. C. E. H. Stone (Chairman), G. R. McArthur, O. K. Mallyon, V. O. Stone, W. J. B. Tuendemann, and J. T. Simper (Hon. Sec.). The offer of Messrs. Stone Bros. of their residence as a meeting place was accepted. It was decided to hold homestead meetings at intervals, and that monthly gatherings should be held on the nights preceding full moons.

**WOODLEIGH, April 26th.—GRADING SEED WHEAT.**—This subject was dealt with by Mr. F. C. Schultz, who advocated the use of the grader. Mr. G. Good stated that on one occasion he graded a bag of oats and removed a cigar box full of charcoal seed. The resulting oat crop was entirely free from the wild mustard. Mr. L. Good also contributed to the discussion.

## SOUTH AND HILLS DISTRICT.

CHERRY GARDENS (Average annual rainfall, 35.03in.).

May 3rd.—Present: 12 members and eight visitors.

HOMESTEAD MEETING.—Members met at the home of Mr. C. Ricks. An inspection was made of the property and proved both profitable and interesting. Fruit trees appeared to have stood the dry season remarkably well. The vegetable garden demonstrated the possibilities of irrigation. Water, pumped from wells with two engines, had been judiciously reticulated through sprinklers. As a consequence the marketable produce was well grown, and the crops were heavy. In the citrus plantation, which depends upon the natural rainfall, trees carrying promising crops were beginning to show the need of water. Afternoon tea was provided, and in the business session that followed Mr. Ricks was congratulated upon his enterprise.

CLARENDON (Average annual rainfall, 33.67in.).

January 25th.—Present: 16 members.

GROWING FODDER FOR STOCK.—Mr. C. C. Spence read a paper on this subject. He emphasized the value of grass land for feeding stock, and advised allowing sheep fed on rape to have access to grass as well. For spring feed he considered that rape and King's Early wheat, followed by field peas, were the best. Wheat and oats should be grown for hay and chaffed before feeding. He calculated that a farm of 160 acres worked in this way would carry three wethers or two and a half breeding ewes per acre in addition to a team of horses and two or three cows. He preferred feeding cows on a mixture of oat hay and mangolds to lucerne. One advantage gained by feeding off crops was an improvement in the quality of the land and in the subsequent crops. The paper was well discussed by those present.

CLARENDON (Average annual rainfall, 33.67in.).

March 8th.—Present: 11 members.

AFRICAN BOXTHORN.—A resolution was carried supporting the Milang Branch in their efforts to have this plant declared a noxious weed.

HARVEST REPORTS.—The Secretary (Mr. T. B. Brooks) stated that he cut 3 tons to the acre of Leak's Rustproof wheat, grown on fallow manured with over 1cwt. S.A. super. A fair cut of the same variety was also obtained from pea ground that had been manured with bonedust the previous year. The bulk of the pea ground returned a very poor hay crop. There was too much wild oats and sorrel. This land had been dressed with 2cwts. slacked lime per acre, but the season had been very dry. Two paddocks were drilled with peas early in July with from 1cwt. to 3cwt. of Thomas' super., and a few acres were dressed with bonedust. The super. plots made the best beginning, but on account of the scanty rainfall, no difference was noticeable between the two lots by the end of September. Oats drilled on June 9th gave a poor return. Apples were a failure. Potatoes planted during the second week of August gave only one-quarter of the return secured from the same land in 1913. He had never known a worse season. Mr. A. A. Harper said his report was not encouraging, owing to the drought. His hay crop cut from one to two tons per acre, and averaged 30cwts. King's Early wheat gave better results than Yandilla King. The oat crop cut from 10cwts. to 30cwts., and averaged 1 ton to the acre. The Algerian variety proved more prolific than the Cape or Calcutta. The pea crop was a total failure, seven bags being harvested, where 10 were sown. The potato crop also failed, two tons of seed producing only 5cwts. of tubers. Mr. F. Shiedow gave the results of seed and manurial tests with potatoes grown in rows 20in. apart, in a plot 53 yards long by 23 yards wide. Fifty-six lbs. potatoes, supplied with 57lbs. potato manure, produced 2cwts. 1qr. 19lbs.; 56lbs. seed with 52lbs. S.A. super., yielded 2cwts. 1qr. 19lbs.; 54lbs. seed with 50lbs. guano super. returned 2cwts. 11lbs.; and 52lbs. seed, with 65lbs. Thomas' super., gave 2cwts. 6lbs. of tubers.

FOREST RANGE (Average annual rainfall, 35in. to 36in.).

April 29th.—Present: seven members.

BLACK SPOT.—This damaging fungus was the subject of a paper written by Mr. H. J. Darwent (Inspector of Orchards), and read by the Secretary (Mr. O. S. Pollard). The writer said:—The fruit season just closed has, in some respects,

been a disappointing one, particularly in regard to the apple crop. Early in the spring there was every promise of a very heavy yield. The setting of the fruit, with the exception of one or two varieties, was very heavy, but the unseasonable weather experienced directly after, had the effect of causing the fungus *Fusicladium dentriticum*, commonly known as black spot, to spread rapidly. A fungus is a plant of the lower order, and differs from the higher plants in that it has no flowers, nor does it produce green coloring matter as in ordinary plants. It forms seeds, known as spores, and also roots, known as mycelium or hyphae. The mycelium causes the damage to trees attacked by fungus; the hyphae find their way through the wood, breaking down the cells and thus destroying the plant. The mycelium sends out branches, each bearing a spore at its end, or a receptacle containing many spores. These are known as conidia spores. The fungus concerned with apple scab is *Venturia inequalis*, and the fusicladium is this conidial or secondary condition of the fungus. The summer spores of the fungus are produced in the way mentioned above. On the shoot it appears as blackish-olive patches, at first covered with the epidermis, which afterwards becomes ruptured. Infected shoots are easily recognised in early spring by the injured bark at the base of last season's growth. At that time of the year the ruptured patches are densely covered by the fusicladium form of the fungus, awaiting suitable conditions for their spread. Wind, rains, &c., are the means which convey the spores from one part of the tree to another. They are carried along the shoots in water to the leaves, which become infected. It is noticed at first on the leaves as small, dark, roundish spots, usually on the upper surface. These spots increase in size until they meet, forming large irregular blotches. At first the mycelium spreads under the skin, which eventually ruptures, exposing fusicladium conidia similar to those produced on the shoots. These conidia are conveyed from the leaves and twigs to the fruit, which in turn becomes infected, the result being apple scab. In the fruit it shows as irregular, slightly sunken patches. Often the fruit cracks; this is due to the fact that the outer portion ceases to grow under the influence of the fungus, and the internal pressure causes the outer unyielding portion to split. The continuance of the wet weather in the spring was the cause of some difficulty in applying the usual remedies to combat this disease; but some growers who applied them early had the satisfaction of preventing its spread to any great extent. Few growers give their trees a heavy spraying during the winter, while the trees are dormant, relying solely on one spraying just as the flower buds are opening. In normal seasons this gives fairly good results—not that it is sufficient to kill the fungus, but chiefly because the weather conditions are not favorable to the spread of the disease. But as prevention is what we seek, it is unwise to leave anything to chance. A spray composed of 1lb. of sulphate of copper (bluestone) dissolved in 20galls. of water, applied directly the autumn leaves have fallen, and followed by the usual spring spraying, has given excellent results during the past season. After the setting of the fruit the trees should be watched closely, and on the first appearance of the disease further spraying should be done. It is important that the leaves be kept free from the fungus, as it is chiefly from them that the spores are conveyed to the fruit. Also, when the leaves are affected, they shrivel and fall prematurely, thereby being prevented from fulfilling their functions, which are so vital to the health of a tree and the production of a good sample of fruit. It is well to remember that this disease can be prevented and kept in check; but when once it has become established on the leaves and fruit it cannot be removed during that season. Various fungicides are used to check diseases caused by parasitic fungi. Bordeaux mixture has given splendid results when properly prepared and applied at the right time, and the lime-sulphur mixture has given satisfaction in the few gardens in which it was used during the season. This fungicide can be procured made ready for use. The object to be aimed at in preparing Bordeaux mixture should be to reduce the lime to the lowest possible proportion consistent with the precipitation of the whole of the copper present; any excess of this means loss of efficiency. It is impossible to adjust the quantity when using milk of lime, but it is perfectly simple by using clear lime water. One hundred gallons of such mixture is prepared as follows:—Dissolve 6lbs. 6½ozs. of crystallised copper sulphate by suspending it in not less than 7galls. of water in a wooden vessel. Take about 3lbs. of good quicklime and slake in a

little water; then put it into a tub with 120galls. of soft water. Stir the lime and water and allow it to settle until quite clear. Run off 86galls. of the clear lime water and mix it with copper sulphate. To reduce to strength of normal Bordeaux mixture make up to 100galls. with soft water. To test whether all the copper in the mixture is thrown down, put a few drops of a solution of potassium ferrocyanide (which may be obtained at any chemist's) into a white saucer with a little water, and drop into this some of the clear liquid after the Bordeaux mixture has settled. A red or brown color shows that there is copper in solution, and more limewater must be added until the test shows no coloration. Bordeaux mixture prepared in this way acts as a fungicide at once, while that prepared with milk of lime will not act for a week or more after spraying. In that time rain may have removed it. The use of lime in preparing Bordeaux mixture converts the bluestone into a basic mixture, which is insoluble. The action of the carbonic acid of the air gradually liberates small quantities of the ordinary sulphate, hence its action is much slower than when only clear lime water is used. Under normal weather conditions the amount of the ordinary sulphate liberated would be sufficient to check the fungus, but in seasons such as the last, which are so favorable to the spread of the disease, it would not be sufficient to cope with it.

HARTLEY (Average annual rainfall, 15in. to 16in.).

March 31st.—Present: 20 members.

SUMMER FODDERS.—Mr. F. Lehmann, in dealing with this subject, referred particularly to crops that could be successfully grown in any part of the district. Maize, he said, broadcasted at the rate of 5bush. to 15 acres over ordinary fallow, would return a crop 4ft. high in a favorable season, and 1ft. high in the driest. The maize would stand harrowing till it was 1ft. high. To produce heavier crops 1bush. of seed should be drilled in through the barley or oats openings, leaving all the holes open. A plot of good soil should be selected, and if sandy super. should be used. Maize sown on the Bremer Flats in October, with 1in. of rain, would make a growth of 4ft. by the end of December; sown in November, with sufficient moisture in the soil to ensure early germination, with 1in. of rain in the middle of December, a 3ft. growth could be secured. This year he had sown maize on drifting sand. While other parts with similar soil were drifting deserts the maize plot was free from drift, and produced a crop from 12in. to 18in. in height. Maize sown on land flooded on December 24th had produced a crop 6ft. high without further rain. Sorghum was hardier, a slower grower, and could not be fed to stock before it had matured. The young plants would not stand the drift sand like maize, but had the advantage of sprouting again after being cut. Rape was more suitable for early summer or autumn use. Given a good start during the early summer it would grow throughout the season. Crops had been successfully grown in the district to provide early winter feed for sheep. He grew maize and sorghum on land that had been cropped for hay during the winter. He had found that a plot at Kanmantoo, assisted with applications of superphosphate, had not deteriorated after 11 years of continuous cropping. Some members thought that maize should be chaffed instead of being fed long.

THE HORSE.—Mr. O. Klenke described the horse as the most useful animal on the farm, providing too many were not kept. On a farm of 500 to 600 acres a man should crop 150 to 200 acres annually with a team of seven horses, including two of a light stamp. A pony or pair should be maintained for use in the trap or sulky. He advised members to use their horses to conserve cocky chaff, straw, and to bind and head portion of their crops. In the discussion that followed some members thought seven horses inadequate for the area mentioned, and that it was more profitable to breed the type required than to purchase them.

LONGWOOD (Average annual rainfall, 37in. to 38in.).

April 24th.—Present: 11 members and four visitors.

HOMESTEAD MEETING.—Members met at the homestead of the Secretary (Mr. J. R. Coles). Inspection of the garden showed that despite the fact that the season had been the driest on record, the trees were in good order, and the young ones had made excellent growth. The marrow-stemmed cabbage (*Chou mouellier*) and Jersey tree kale had succeeded admirably.

**EARLY V. LATE HATCHED CHICKENS.**—Mr. E. W. Beythien quoted figures obtained from experiments with early and late hatched chickens. Twenty-five pullets hatched on August 1st, 1913, started to lay when five months old, as follows:—December, 1913, 23 eggs; January, 1914, 306; February, 462; March, 385; April, 231; May, 167; June, 349; July, 428; August, 568; September, 573; October, 602; November, 495; December, 363; January, 1915, 316; February, 285; March, 123. The total eggs laid from hatch to real moult was 5,678, or an average of 227 per hen. The cost of food per hen from April to April was 7s. 10d. Valuing the eggs at 1s. 1d. per dozen the return per bird was £1 0s. 5.24-25d. Thirty pullets hatched on September 1st, 1913, began to lay at five months, as follows:—January, 1914, 19; February, 269; March, 440; April, 491; May, 198; June, 302; July, 570; August, 744; September, 665; October, 707; November, 575; December, 441; January, 1915, 320; February, 312; March, 126. The number of eggs laid was 6,179, or an average of 206 per hen from hatch to moult. Taking the average price of eggs at 1s. 1d. per dozen, the return per bird was 18s. 7d. Thirty pullets hatched on October 1st, 1913, opened their egg-laying account when six months old, as follows:—March, 1914, 157; April, 203; May, 250; June, 553; July, 662; August, 768; September, 697; October, 718; November, 579; December, 467; January, 1915, 442; February, 339; March, 127. The aggregate production was 5,942 eggs, or an average of 198 eggs per bird from hatch to moult. The average return was 17s. 10d. Twenty pullets hatched on November 1st, 1913, started to lay at seven months, as follows:—May, 1914, 1; June, 182; July, 406; August, 449; September, 426; October, 437; November, 378; December, 314; January, 1915, 274; February, 248; March, 169. The total of 3,284 eggs laid gave an average per bird of 164 eggs, and a return in cash of 13s. 8d. per hen. Forty-five pullets hatched on April 1st, 1914, laid when five months old. Their production was as follows:—September, 287; October, 1,053; November, 987; December, 686; January, 1915, 500; February, 496; March, 201. The total, 4,210 eggs, gave an average of 93.5 per hen, which with the average price of eggs at 10d. per dozen, returned 6s. 4d. per bird, or insufficient to pay for their keep with foodstuffs as high-priced as at present. The April set eggs cost twice as much to incubate as the spring hatchings, the percentage of chicks being 33 per cent. as against 66 per cent. Mr. Beythien, in conclusion, said he was convinced that it did not pay to hatch chickens after October 1st.

**THE BEGINNER IN THE DISTRICT.**—Mr. J. C. Blakely read a paper on this subject. He considered that until the new settler had gained local experience he should curtail his programme. The Agricultural Bureau meetings were invaluable, as they gave him opportunities to profit from the knowledge of others. Members generally agreed with the references to the Bureau, and one member with 20 years' connection said it had helped him more than anything else to succeed on the land.

**REMARKABLE GROWTHS.**—A member mentioned having grafted Wright's Early plum on apricot tree butts, and the growths in April were 12ft. long. Some potato tubers with a strong grass, resembling couch, growing through them were tabled.

**MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).**

March 30th.—Present: six members and four visitors.

**HINTS FOR FARMERS.**—Mr. H. J. Wiadrowski pointed out that a more general use of the binder and thresher in harvesting would save more grain and fodder than it was possible to do with the stripper or harvester. Care in keeping implements and harness in tip-top order paid handsomely. A good dressing of oil or grease should be applied to harness at least once a year. Grading seed wheat was recommended. He suggested that farmers should conduct a few experimental plots and keep the records from year to year.

**TO CURE KICKING.**—Mr. A. Stirling, jun., said the vice among horses was often constitutional. He considered that careful training and treatment during the period of colthood was the best preventive.

**MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).**

April 27th.—Present: five members and two visitors.

**ROOT CROPS ON THE FARM.**—This subject was dealt with by Mr. Williams, who said the objects to be aimed at were:—(1) To provide for the livestock; (2) to give a rotation with cereals; (3) to supply the kitchen with vegetables; and (4) to raise a money crop for any accessible market. A few acres of suitable

roots enabled the farmer to sell more of his cereals, as he required less hay. The roots commonly grown in the district were turnips, swedes, mangold wurzels, and potatoes. Turnips succeeded best in light soils, well manured with bone-dust or super. Cultivation recommended was:—Sow the seeds thinly in succession from March till June in shallow drills, 15in. apart, thin out the plants to 8in. in the rows, and pay attention to hoeing and weeding. Similar cultivation was necessary for the swede turnip, except that 18in. should be allowed between the rows and 12in. in the rows. Swedes, unlike turnips, could be successfully transplanted. Mangold wurzels were valuable as feed for cows and pigs. The long varieties, long red and mammoth, succeeded best in rich loamy soil, deeply worked and highly manured. The addition of 2cwt. of salt to the acre improved the yields. The seed should be sown in drills 2ft. apart, at the rate of 7lbs. to the acre. The plants should be thinned out to about a foot apart, be well cultivated, and kept free from weeds. The globe varieties were more suitable for light soils. Seed could be sown at the commencement of the rainy season or during August and September. Only potato seed with sturdy shoots should be planted. Small tubers about the size of hen eggs were the most economical. At planting time the sprouts should be 1-16in. long. The soil should be open, easily worked, and improved by the application of well-rotted stable manure. Land heavily manured for the production of cabbages or similar gross-feeding crops was well adapted for autumn potatoes. When super. was used the method followed was to spread it in the furrows with the sets, at the rate of 10cwt. to 1 ton per acre. Broadcasting before ploughing answered very well when the sets were to be dibbled or plough sown. A good friable soil enriched with an initial 12cwt. of bone super. and 2cwt. of muriate of potash when the plants were hoed for the last time, provided excellent conditions. Ordinarily the distance between the rows was three furrows (2ft. to 2½ft.), and the spacing in the rows was from 12in. to 20in., according to the varieties. Up-to-dates, Prolifics, and Pink-Eyes did not require as much room as Snowflakes. When the plants had grown sufficiently to clearly define the rows the plot should be harrowed to preserve tilth and kill weeds. When 4in. high the ground between the rows should be worked with a horse cultivator or by hand. The soil between the plants should be stirred with the hoe. Hilling, if necessary, should be done before there was any danger of covering the foliage or damaging the young crop. When the potatoes became firm-skinned they were fit to dig. The roots mentioned, with the exception of white turnips, would store well in the open after digging, if protected against dampness. He recommended testing all seeds for field planting. A germination test was easily carried out in boxes of finely pulverised soil, kept slightly damp, in a temperature of about 70 degrees Fahr., or by placing the fine seeds on a strip of damp cloth, placed on a plate, and covered with another plate or piece of glass. Larger seeds could be placed between the folds of the cloth. In both cases the temperature of the living room would be suitable for germination.

#### MORPHETT VALE (Average annual rainfall, 23.32in.).

November 19th.—Present: 11 members.

POULTRY.—Dr. Newland read a paper on this subject. He traced the domestic hen back to its origin, and described its improvement from a producer of one or two sittings of eggs a year into an "egg-laying machine." He outlined the methods of feeding and the lines of breeding. For hatching chickens he preferred the incubator to the hen. He emphasized the importance of cleanliness. In conclusion he said:—"In marketing the produce cleanliness and quality are necessary. The nests should be clean, then egg washing will not be required. For table poultry market the birds fat and young. Young poultry is worth twice as much per lb. as old; fat birds twice as much as thin. If quality is there 1s. per lb. live weight can be reckoned on for the lighter weights, for a large bird is not wanted. The most I have got for four months to five months old cockerels is 4s. 10d., and I have got an average of 2s. 9d. for birds that would average but very little over the 2lbs. live weight. With eggs, storage in some form (cold or in waterglass) should be resorted to when the price falls to about 8d., or even before this. It is a bad year indeed when pickled eggs will not bring 1s., and eggs cold stored bring only a penny or so less than fresh eggs. Infertile eggs alone should be marketed."

## MOUNT BARKER (Average annual rainfall, 30.93in.).

March 31st.—Present: 43 members.

In reply to questions it was stated by members—

1. That 10 tons to 15 tons of farmyard manure per acre, with 3cwt. of super, would give good results.
2. That the district was too cold to grow a combination of wheat, oats, and lucerne for hay. Lucerne by itself thrived well.
3. That wheat, poisoned with potassium cyanide or strychnine, sown along the headlands, was a good protection for crops against the ravages of birds.
4. That King's Red was a mid-season wheat, was bearded, and good for hay or a dry country.
5. That water equivalent to 8in. to 10in. of rain, would be required to irrigate an acre of green forage for four months. Flooding the land was better than using the sprinklers, as the water soaked through to the subsoil.
6. That it would only be profitable to manure land that had been manured last season if the coming season was a wet one. Manure could safely be used either with the seed or afterwards as a top dressing.
7. That a good disc cultivator, in preference to a spring-toothed one, would be equal to the plough this year for early sowing.
8. That the best way to get rid of wild oats was to cultivate now, then harrow, and later on plough in for crop.

## MOUNT BARKER (Average annual rainfall, 30.93in.).

April 29th.—Present: 39 members.

MANURES AND FERTILIZERS.—A comprehensive paper on this subject was read by Mr. J. E. Smith, as follows:—The object of manuring is to assist the soil in presenting to the plant a portion of the food necessary for its growth. *Phosphoric Acid*.—For bone phosphates the coarser kinds of bone meal are converted into dissolved bones by being mixed with enough sulphuric acid to convert about half of the phosphates in the bones into a soluble condition; that is, we get a substance resembling the common mineral superphosphate. Bone dust is rather slow in giving up its phosphoric acid, probably because of its comparative coarseness, and the consequent small surface of the manure particles offered to the solvent action of the soil water. The discovery that treating bones with sulphuric acid renders the phosphate of lime soluble, and so the phosphoric acid at once available, was announced in 1840 by Baron Liebig. Sir John Lawes, the founder of the famous Rothamstead experiments, was granted a patent in 1842 for making phosphate from the rock. The rock phosphate of lime is crushed, then ground to a fine powder. A weighed amount of this fine powdered tricalcium phosphate is put into a mechanical mixer, an exactly calculated quantity of dilute sulphuric acid is poured in, and the two are rapidly mixed. The result is a hot, sloppy, sludge-like material, which is dropped or emptied into a special chamber, where it solidifies as the chemical combinations are completed, and is then superphosphate. The quantities of the substances to be used are calculated so exactly that the material is very friable, easily crushed, and dry enough to run through a fertilizer drill. The friability is caused by leaving a little free tricalcium phosphate undecomposed. This combines with a little of the acid phosphates, and makes another phosphate, intermediate between the tricalcium and superphosphate. These three forms may be represented thus:—(1) The phosphatic rock is tricalcium phosphate; that is, three parts of lime combined with phosphoric acid. This tricalcium rock is called "insoluble," i.e., it is insoluble in weak acids or water. (2) Dicalcium phosphate consists of the original tricalcium phosphate, with one part of lime replaced by water. This is soluble in weak solutions of citric acid, and known as citrate soluble. When ordinary superphosphate is applied to the land it tends to revert to this form, but so finely is it ground, that the particles can be made use of by plants. (3) Add sulphuric acid to the tricalcium phosphate above and the ordinary superphosphate results. Thus, the original lime now forms the lime in the superphosphate, and also the lime in the by-product. The manufacturer tries to make a product containing 17 parts super, 1 part of the citrate soluble, and 2 of the acid soluble rock. About 1 ton of rock and 1 ton of dilute sulphuric acid are used to make 2 tons of super. Many iron ores contain phosphorus, and this is fatal for cast iron products. To remove this phosphorus the furnace is lined with lime, and lime and magnesia are added to the ore to form a base with which the phosphoric acid from the iron will combine,

leaving the iron free. The resulting slag contains quantities of phosphoric acid varying with the ore; i.e., about 12 to 23 per cent. The slag is ground so finely that 80 per cent. passes through a mesh having 10,000 holes per square inch. An analysis shows that Thomas's phosphate may contain:—Lime, 41.58; magnesia, 6.14; alumina, 2.57; iron oxides, 18.70; manganese, 8.54; silica, 7.38; sulphur, 0.66; calcium and phosphoric acid, 14.36. As a fertilizer it is about equal to the citrate soluble phosphoric acid in super. Where there is moisture enough it is valuable as a top dressing for pastures; for leguminous crops it is a good fertilizer, but is not suitable for dry country, though very suitable for acid soils or soils deficient in lime. Guano is a term covering a wide range of fertilizing substances. The word is derived from the Spanish "huano" (dung), and, properly, is restricted to the excreta of sea birds. Hall says:—"It is a safe manure, applicable to all crops, and not requiring the skill in its adjustment to the land or the crop which is necessary with the more active manures like nitrate of soda, etc. Again, coming into action continuously and equably, it is more calculated to yield produce of high quality than more concentrated manures; it is therefore suitable, especially for fruit crops." *Use of Phosphates.*—Again, quoting from Hall's *Manures and Fertilizers*:—"Just as nitrogen delays maturity by promoting growth, phosphoric acid has an opposite effect; it is in some way closely bound up with grain formation, being always found in greater proportions in the reproductive parts of the plant than elsewhere. Phosphoric acid increases the proportion of grain to straw, and decreases the nitrogen content of the grain. The action of phosphoric acid on the plant is not confined to its ripening effect; it stimulates the early development of the young seedling to a remarkable extent." There can be little doubt but that this explains why a phosphatic manuring has such a valuable effect in establishing the plant, even if the gross yield is not ultimately advanced. It may also go to explain the extraordinary results of quite small dressings of phosphoric acid upon soils in South Australia, where a manuring of half a hundredweight per acre, or even less of superphosphate, has sometimes been found to double the yield of cereals. It seems much more likely that in a semi-arid country, where the whole success of the crop depends on the roots getting quickly down to the cooler and moister subsoil, the stimulating action of the phosphoric acid upon the young roots becomes of the utmost value. The acid enables the wheat plant to mature with a smaller supply of water than is otherwise required. It also appears to exert a beneficial influence upon micro-organisms of the soil, which render nitrogen available. *Nitrogen.*—Aikman says:—"Of manurial ingredients nitrogen is by far the most important, and on the presence and character of the nitrogen it contains, the fertility of the soil may be said to be the most largely dependent." Hall says:—"Among the elements of the nutrition of the plant the first place must be given to nitrogen; not only does it cost more per pound, but as a fertilizer applied to ordinary soils it seems to have a more direct and immediate effect upon the plant." Renard says:—"Nitrogen is clearly the most important element of plant food. Summed up briefly, it is a case of no nitrogen, no growth." The natural source of nitrogen is the air—four-fifths is nitrogen. The bacteria that cause nitrification do their best work at about 100deg. Fahr.; they cease work below 41deg. Fahr. and above 130deg. Fahr.; so Australia has a distinct advantage in the climate of her wheat-growing districts. If the natural sources of nitrogen are not sufficient, artificial ones must be resorted to. Nitrate of soda, as manufactured for export, contains about 95 per cent. of pure nitrate, of which about 16 per cent. is nitrogen available for plant use. It is soluble in water, and therefore is easily leached out of the soil. For this reason it is best used as a top-dressing, but as it will scorch or destroy green tissue, care should be exercised not to allow it to come into contact with the foliage of plants, unless it can be completely washed off. Nitrate of soda may be mixed with other fertilizers except super., the acid of which gradually liberates nitric acid—the valuable plant food constituent of the fertilizer. If mixed with super. it must be applied to the land immediately. The nitric acid is made use of by the growing plant, and the soda left behind acts on the potash compounds in the soil, and helps to render them available. On heavy soils, the free use of the nitrate tends to make them sticky when wet, and to cake hard when dry. Its special value is its immediate availability. Sulphate of ammonia, when pure, contains about 21 per cent. of nitrogen. If mixed with lime, ammonia is liberated, therefore it must never be used with Thomas's phosphate. A too liberal supply of nitrogen, by forcing vegetative

growth, is often prejudicial to crops. *Potash*.—Four forms are used—Sulphate of potash, muriate (chloride) of potash; kainit, and 30 per cent. potash. Up to the present time the use of potash fertilizers in Australia has been very small. Orchardists and potato growers know its value, but experiments with wheat do not seem profitable. Hall says:—“When potash is deficient the manufacture of carbohydrates, like starch, sugar, and cellulose, is greatly reduced, and in practice it is the crops rich in carbohydrates which are most dependent upon a full supply.” This explains the value of potash for potatoes. On leguminous crops and clovers their action is most striking. *Farmyard Manure*.—Farmyard manures are far from constant in composition, varying with the animal, the food, and the litter. If ammonia goes from the farmyard manure, the chief fertilizing element has gone; the problem is how to retain it. To preserve the ammonia, in the first place the dung must be protected from evaporation; the more exposed the surface the greater the amount of ammonia lost. Several remedies have been suggested:—(1) Mixing the manure with gypsum; that is very expensive, and a product may result very injurious to plants. (2) Adding a good coat of earth to each lot of manure acts well. (3) Keep the manure heap under cover, and pump the urine over it frequently. (4) Best of all, I think, cart the manure straight away to the land and plough it in. Experts recommend that the manure be applied to the land as long as possible before the crop is put in. A mixture of the dung with fertilizers is advised. Twenty loads of dung and 1 cwt. of sodium nitrate, with two or three cwt. of super., is much more effective than, say, 40 loads of dung. A Rothamstead experiment showed an increase of 14.9 tons of mangolds per acre with the former as compared with the latter manure. Of course farmyard manure carries weeds and diseases to some extent. Its value is by no means confined to its fertilizing action—its physical effects upon the texture and water-holding powers of the soil are very important. The rotten manure restores humus to the soil. To sandy soils it gives cohesive and water-retaining power, whilst by loosely binding together the finest particles of clay soils it renders them more porous and friable. It also increases the water-carrying capacity, and hence the drought-resisting properties of the soil. An old English saying, “Muck is the mother of money,” is very true, but hardly appreciated out here. *Green Manure*.—By green manuring is meant the growing of a crop for the purpose of ploughing it in to add organic matter to the soil, and improve its physical condition; used chiefly in orchard work and where intense cultivation is in vogue. For green manure it is always recommended that a leguminous crop should be grown and ploughed in. A writer suggests that the common burr trefoil, sown before the first rains, with lime and super., is one of the best crops to grow for green manuring. Of all the clovers, this is the first to come; it makes the best growth in winter and early spring, is very hardy, and gives a good supply of green stuff for ploughing in. *Laws of Rational Manuring*.—(1) A deficiency in any one of the essential elements of fertility seriously lessens the fertilizing power of the others. (2) To secure larger crops and permanent improvement of the land, phosphoric acid, potash, and lime should be used in greater quantities than the crops require, but nitrogen should be used in amounts not in excess of the needs of the crop. (3) The greatest yields may be obtained from quick-growing crops which have only a short period to mature when the soil contains an excess of all the elements of plant food above the requirements of the crop. (4) Having regard to the widely different natures and requirements of soils, the system of using complete manures adapted to meet the needs of the special crop desired, is to be preferred to that of using fertilizers to meet the special conditions of each class of soil.

#### MOUNT COMPASS.

May 1st.—Present: 14 members and two visitors.

**BINDER TWINE IN CHAFF.**—Mr. D. Hancock drew attention to the prevalence of binder twine in chaff. Other members had also observed many twine knots in chaff; they thought that possibly some of the ailments of stock were more or less due to its presence. It was resolved—“That it is desirable to make it compulsory to remove twine before sheaves are chaffed.”

**PREPARATION OF NEW LAND.**—This subject was introduced by Mr. C. J. Skews. Dealing with new scrub land, he advised cutting the scrub close to the ground in the spring, and on large areas using the roller. In February the timber could be burned, when it would check the growth of many shoots from the

living roots. Strong shoots could be slashed prior to the burn. If the land was not required for cultivation at once, systematic cutting of shoots would in a short time weaken the stumps, which would then grub easier. For breaking new scrub land he preferred the S.J. disc plough, with plenty of power attached. Loamy soils should be ploughed to a depth of 6in. or 7in. He would harrow with the first rain, and work the land up well before sowing a crop. In no case should the land be worked in a wet state. He preferred sowing oats early in April, if the weather was suitable. He would roll the land (if dry) after the crop was up. After cropping it was advisable to run the firerake over the stubble to scorch shoots. To clear a new swamp, already drained, he would run a light fire through it first, skim all rushes below the ground with a special hoe 7in. by 4in., grub out all titree and wattles, finally firing the timber and rubbish when thoroughly dry. Care was necessary or the swamp itself might be set alight. If the ground would bear the weight of a horse he would turn it up with a specially sharpened single-furrow plough, taking each furrow twice. If soft, the ground required working up with a strong hoc. Root crops like potatoes, turnips, and swedes would thrive on this new land if manured with bonedust. Mr. Hutton considered surface draining of paramount importance. The Secretary (Mr. Wellesley Cocks) said rolling and burning, followed by two good disc ploughings, constituted the only economical method of clearing the local scrub lands. He had got the best results the first year by leaving the land fairly rough.

CO-OPERATION.—This subject was discussed. Mr. M. Jacobs advocated making a practical start by co-operating to send surplus produce to distant markets by rail, and pooling orders for super., &c., so as to ensure obtaining the best prices and the lower rates for truck lots.

#### MYPONGA.

February 3rd.—Present: seven members.

MIXED FARMING.—Mr. McGuinness read a short paper on this subject, in which he stated that land in the district was seldom worked enough. He gave the results of an experiment with 1 acre carefully worked for 12 months before last seeding. It was sown with 1bush. of King's Early wheat and ½cw. guano super., and was cross-drilled with 1bush. Algerian oats and ½cw. guano super. The yield, over 3 tons of hay, was double the return from similar land under ordinary treatment. Irrigation, to produce fodder crops for cows and sheep, was not practised enough. It would also pay to breed more horses. Members generally agreed with the writer. The same subject was dealt with at the March meeting by Mr. Everard. He said raising crops to feed to stock could be profitably carried on in the district. Heavy cereal crops could be grown. Last year he had fed off a barley crop for 3½ months, and carried six sheep to the acre for that period. The barley was then allowed to mature, and averaged 4bush. to the acre. After harvest it carried 300 lambs and 20 horses for one month. Forage crops would grow at a tremendous pace if planted in spring or early autumn. He had seen two crops, one of them hay, grown in the district off the same paddock in one season. Maize, rape, peas, and lucerne all succeeded admirably in the district. At Aldinga one year rape carried 10 sheep to the acre for the year. More attention could profitably be paid to the cultivation of English grasses, such as clovers, rye grasses, &c. The mixed farmer could also grow potatoes as a main crop, for 7-ton to 8-ton yields were common, and double that return was not unusual. Most of the hill country was suitable for the production of apples and pears. Small fruits and vegetables of all kinds could also be grown to perfection. Nothing but laziness or short-sightedness could prevent any man in the district from succeeding in a fairly wide range of mixed farming.

#### NARRUNG (Average annual rainfall, 17in. to 18in.).

April 3rd.—Present: eight members.

GREEN FODDER.—Mr. L. Bowyer read a paper on this subject, dealing particularly with barley, oats, rape, and lucerne. He preferred to sow barley and oats mixed on rich hay stubble land, treated by deep ploughing in March before the rains, and fine harrowing. He would dry sow 1bush. each of oats and barley in

readiness to catch the first rains. From the time the crop was 4in. high till August, it could be fed off by stock, and then the subsequent growth could be preserved for hay. He had secured a lot of early feed in February and March from rape by sowing about 3lbs. of seed to the acre early in August amongst the cereal crops intended for hay. After the sowing the crop was rolled. The binder would cut off the tops of the rape, which would shoot again. If the cereals were left for grain the rape would not interfere with the stripping. Lucerne was the best of all green fodders for early or winter feed. He advocated ploughing to a depth of 6in. or 7in. when preparing the land for sowing. Oats, sown at the rate of a bushel or less to the acre, made a good nurse crop, especially if the situation was exposed. He preferred giving the oats a start of one month before sowing the lucerne seed. After the second cut he fed the lucerne off, as it saved a lot of work.

#### PORT ELLIOT (Average annual rainfall, 20.33in.).

April 17.—Present: five members.

GENERAL.—Mr. J. Brown, son., said the best way to use stable manure was to cart it straight from the stable on to the land. The only objection to that course was that it promoted the growth of weeds. Members thought the best plan was to let the manure rot in the heap before carting it to the fields to be ploughed in at once. In reply to Mr. McLeod's question whether brackish water, used for lucerne plots, should be distributed by sprinklers or flooding, Mr. Brown recommended that the latter method be adopted a few days before cutting.

DUTY OF MEMBERS.—The Secretary (Mr. H. B. Welch) dealt with this subject. He said members should endeavor to carry into effect on their farms and orchards practices and methods learned at meetings of the Bureau. He preferred growing lucerne and summer forage to holding large stocks of hay over from one season to another. Some members had demonstrated the value of this advice by practical irrigation. Members should set their neighbors an example by having substantial fences and good gates. Light iron gates were the most effective and economical. Members should also set an example in tree planting on the farm and in protecting their machinery from the weather. Every member should be watchful in preventing the spread of useless weeds, and should experiment with forage crops. During the droughty summer he had found Scotch thistles a stand-by for the stock.

#### URAILDA AND SUMMERTOWN (Average annual rainfall, 44.35in.).

April 6th.—Present: 14 members.

VEGETABLE GROWING.—This subject was introduced by Mr. J. Little, who said the best varieties of potatoes were Up-to-dates, Carmens, Pink Eyes, and Bismarcks for early crops, and Snowflakes, Up-to-dates, and Prolifics for late planting. A fair coating of stable manure and a dressing of bonedust should be given before the soil was finally dug over. The most profitable early and late onions were the Brown Spanish and the Globe respectively. Rich loamy soil which held the moisture was required for these crops. Tilthy deep loamy soil was excellent for carrots and parsnips. He recommended digging in some bonedust and thoroughly incorporating it with the soil in addition to placing a light covering of stable manure over the surface. Late carrots should follow on early lettuce or cabbage crop, and the seed should be sown shallow after the soil had been nicely worked up. A light coating of stable manure would assist growth. Cabbages required good soil and plenty of manure and water. For early cabbage he advised planting on a warm sheltered bank dressed with a fair coat of stable manure, 4cwt. of bonedust, and ½cwt. of ammonia to each 1,000 cabbages. The most reliable peas were the Yorkshire, the best French beans the Dwarf Canadian, and the best lettuce the New York. In the discussion that followed Mr. C. Oliver deprecated the practice of digging in manure prior to sowing carrots. He preferred digging in a heavy application before sowing the previous crop. Mr. F. H. Stacey preferred the Snowflake variety as a late variety for planting about Christmas. Mr. J. Bonnython said the white onion was the most profitable commercially. Mr. J. Rowe also contributed to the discussion.

CLARENDON, January 4th.—A paper treating with co-operative fruit-picking, grading and packing, written by Mr. W. B. Burpee, was read by Mr.

E. Burpee, and was fully discussed. The writer said the small orchardist labored under a disadvantage in exporting fruit, as it was impossible to grade them without a mechanical grader. Under the co-operative system a plant could be installed in an inexpensive building erected in a central position, which suppliers could conveniently reach with their produce, especially apples and pears. Expert packers could be trained in the district, and the whole of the fruit be graded and packed to secure uniformity—which meant higher prices. Mr. J. Spence favored the suggestions. He considered that greater care should be taken in picking the fruit.

INMAN VALLEY, April 29th.—Mr. H. T. Martin's paper on "Fruit Cultivation," previously published in the *Journal of Agriculture*, was read. Mr. H. Gray submitted a practical paper dealing with "Pig-raising." He recommended the mating of selected Berkshire sows, when 12 months old, with Essex boars. He allowed breeding sows the run of a small paddock, and penned them a fortnight before delivery in warm, clean sties. Too much bedding was likely to cause the young to be smothered. When the piglets were eight or nine days old he made a small hole in the sty to allow them to run in and out. He found they thrived better when this was done. When a month old the young pigs were given a little milk in a low trough, or a little wheat and peas sprinkled over the ground outside the sty. They should be weaned when seven weeks old, and a week later, or as soon as possible thereafter, the sow should be mated again. Milk or thin pollard should be given when the young pigs were weaned, with a little grain once a day. Well fed from the start, they would be worth 30s. to 35s. each when four months old, and should weigh from 65lbs. to 70lbs. In the off season piemelons, small potatoes, screenings, or pea stubble made an inexpensive food for the sows. Profitable discussion followed. Mr. H. T. Martin exhibited a fire-lighter, designed by himself, for the purpose of setting alight rubbish heaps in the fields.

IRON BANK, April 26th.—Mr. W. Coates read an interesting paper dealing with the value of common salt as a fertilizer.

KANMANTOO, May 1st.—IMPROVING BUREAU MEETINGS.—The Secretary (Mr. Seabert C. Downing) read a paper on this subject, written by Mr. R. Critchley. The writer urged members when submitting a paper to give "straight-out, practical opinions." He suggested that once a year the neighboring Branch should be invited to a meeting to discuss farm work generally.

MEADOWS SOUTH, March 30th.—THE COMING WINTER.—Mr. S. Smith read a paper on this subject. He advocated rugging stock, and considered that every landholder should sow as much land as possible with a variety of fodders. In the discussion members generally agreed that the Chevalier barley was the best to sow for early green feed.

MEADOWS SOUTH, April 27th.—QUESTIONS.—Mr. A. E. Maidment asked if it was advisable to cross-drill for a hay crop. Members considered the practice a good one. Mr. Philpot inquired what was the best manure to produce a hay crop. Bonedust was considered the best all-round fertilizer for the district. The Chairman wanted to know the best means to induce pigs to eat readily. Mr. Stone suggested turning the animals out for a while to forage for themselves. Mr. Nicolle exhibited a milk-fever outfit, with which he had cured some apparently hopeless cases.

MOUNT COMPASS, January 30th.—Members reported that "riddlers" and green aphides had done extensive damage, especially among cabbages. Mr. Jacobs said that prior to planting out seedlings he had dipped them in a weak solution of arsenate of lead with good results. The Inspector of Orchards had recommended spraying with tobacco wash to destroy the aphides. The Secretary (Mr. Wellesley Cocks) exhibited samples of maize and rape grown on the Government experimental plots. Members considered the results to be exceedingly satisfactory.

MYPONGA, April 28th.—The subject of co-operation was discussed. Members agreed that benefits should follow co-operative efforts in purchasing supplies, but the majority considered that farmers preferred selling in the open market, and would not be loyal to a union devoted to buying and selling. Mr. Hooper favored supporting the South Australian Farmers' Union, providing they would act as agents for the Bureau. Several members favored obtaining supplies in bulk to secure lower prices and railway concessions.

STRATHALBYN, March 30th.—It was decided to support the Milang Branch in their endeavors to have African borthorn placed on the schedule of noxious weeds. Mr. A. Beviss read an interesting paper on the drinking capacity of cattle in the far north.

STRATHALBYN, April 27th.—An instructive paper on the Brands Act was read by Mr. R. M. Tucker. Methods of pickling seed wheat were discussed, members favoring bluestone.

## SOUTH-EAST DISTRICT.

GLENCOE (Average annual rainfall, 33.84in.).

April 26th.—Present: nine members and one visitor.

FERN DESTRUCTION.—Mr. J. Barry recommended the ploughing under of ferns in March, and the sowing of the land with Algerian oats. By cutting the crop a considerable check would be given the ferns. Constant treatment was necessary to ensure extermination. Burning was of little use, except after the first rains, as heavy frosts in the winter sometimes gave the tender fronds a serious check. Once the land was grassed cattle assisted to check the ferns by camping in the patches. Pulling up ferns in the crops was effective but laborious. The President (Mr. J. Dow) advocated running the mowing machine over the patches twice a year. Mr. H. A. Cameron had seen capital results gained by ploughing the ferns under in summer. Mr. J. Riddoch said mowing was preferable to ploughing as it was quicker and did not injure the grass. A vote of thanks was carried at the instance of Messrs. G. E. Copping and H. A. Agnew.

MOUNT GAMBIER (Average annual rainfall, 32in.).

February 13th.—Present: 15 members.

RAPE FOR FODDER.—In reply to a question on this subject Mr. D. A. Collins said he had found it best to sow rape during the first week in September, and then it would be ready to wean their lambs on. Mr. A. A. Sassanowsky remarked that he had fed his sheep extensively on rape without loss this year, but it was imperative to have dry feed with it. Sheep should always have access to dry grass as well as rape, otherwise losses would occur.

LAMB INDUSTRY FOR THE FARMER OR SMALL GRAZIER.—Mr. A. A. Kilsby read a paper on the above subject, as follows:—"Dealing with the crossbred or comeback ewes for breeding purposes, it is best to select ewes from three to five years of age, large-framed, and of a strong constitution, and with a good quality of wool. I recommend mating during the third week in December, so that the ewes will commence lambing about the end of May or the beginning of June. Thus, by taking advantage of the early rains and the feed, the ewes have a good flow of milk, and the lambs are, in consequence, well nourished in their infancy. If properly looked after lambs should be ready to sell when from 4½ to 5 months old. I prefer Lincoln rams to mixed breeds for anyone who is keeping sheep for wool, and who is not likely to get all their lambs off, as mixing the breeds results in a falling off in the weight and quality of the wool. To those who sell all their lambs to the freezers or butchers, I would recommend Dorset Horn, Shropshire, Romney Marsh, or Border Leicester, because these mature earlier than the Lincolns. In selecting rams, large-framed sheep, with as fine a head as possible, should be chosen. To get an even lambing the flock should consist of about 2 to 2½ per cent. of rams. The most important matter in the rearing of fat lambs is the pasture. Oats or barley in winter, and natural feed in the spring, should be sufficient. Fodder crops such as rape, kale, and mustard can be sown in the spring, but lucerne or even a good stubble paddock is of great value to any lambs that may not be fit to sell when the bulk of the lambs are marketed. A good idea when ewes are lambing is to cut off those with young lambs from the flock every few days and put them in a paddock by themselves where they will not be disturbed by the ewes which have not lambed. By so doing the lambs are of more even size than when they are all left together. If a ewe has a dead lamb and there is a motherless lamb, by putting the ewe and lamb in a small enclosure for a few days, and frequently catching the ewe and letting the lamb suck, the ewe will soon take the lamb as her own. The lambs should be sold as soon as they are fit, and whilst

the bloom is on them. I believe in marking lambs fairly young, at from four to five weeks' old, because this acts as a check for some time on the older lambs. Lambs should not be marked when it is hot, or when they have been overheated. I would suggest drafting the lambs by themselves into a clean yard. Handle them as carefully as possible, and let them out to their mothers again as soon as possible. It is a great mistake to overstock paddocks with sheep, as by this means the quality of the stock is lowered. A few sheep properly kept will return more to their owner, and at less expense. A change of feed, especially to ewes and lambs, is often as good as a dose of medicine."

#### MOUNT GAMBIER (Average annual rainfall, 32.00in.).

May 12th.—Present: 19 members.

**LIME.**—The Secretary (Mr. D. A. Collins) stated that a sample of powdered lime from Mr. Wilson, of Glenburnie, had been sent to the Roseworthy Agricultural College for analysis. The result was:—Soluble matter, 53.99 per cent.; lime, 23.71 per cent.; equivalent to carbonate of lime, 42.71 per cent.

**THE BACON PIG.**—Mr. J. Keegan read a paper prepared by Mr. F. C. Grace, who dealt with the feeding and care of the bacon pig from birth to maturity.

**EXPERIMENTS IN POTATO CULTURE.**—Mr. R. Fowler said potato culture was not progressing when they imported over 70 per cent. of the tubers required in the State from Victoria. He suggested that the Director of Agriculture should be asked to include some potato plots among the agricultural experiments being carried on in the district. Mr. E. S. Alcock said the Government would superintend the planting and ensure a fair average rent for the land. Surely one of the members of the Branch would be able to provide a piece of land. Mr. Fowler said five acres would be enough. Mr. Sassanowsky moved that the discussion be postponed to next meeting, and in the meantime some of the members might find a block, and the Director might be written to asking if he would care to have the potato experiments carried out in the Fodder Experimental Blocks. Mr. Fowler seconded. Carried.

#### NARACOOORTE (Average annual rainfall, 22.60in.).

December 12th.—Present: 15 members and one visitor.

**VEGETABLE GROWING.**—Mr. W. G. Haynes read a paper on this subject, as follows:—"All seed should be tested by the grower. This can be done by sowing a few seeds before distributing any large quantity. It is advisable to produce our own seed as far as possible. Cabbage seed.—Select a head true to name and perfect type, not necessarily the largest in the bed, cut it, split the stem, and from the young shoots select your seed. Be very careful that there are no other varieties growing near to inoculate the seed. Cauliflower can be treated the same way. Turnips and all kindred sorts.—Select a good-sized true-typed, symmetrically grown specimen. When quite developed pull it and leave it in a shaded place for about a month or so, then plant again, and keep the seeds from these plants. The object for thus treating the parent stock is to ensure a longer period of development before the plant begins to mature; or, in other words, to prevent the progeny from going to seed too quickly, and thus get a longer period of development. Onion seed.—Select an onion that has kept well, and is true to name. Plant it about July, and obtain seed from that. It is advisable to pull the seed knobs before they are quite ripe, and tie them up still on the plant, in small bags, and you will then lose no seed. If left until quite ripe it will nearly all shake out. A good onion is obtained by planting alternate rows of Golden Globe and long-keeping Brown Spanish. This is done by the biggest onion grower in this State. Onion seed will keep good for three years, but it is best to have it fresh each year. Tomato seed should be selected from one of the first tomatoes to ripen. Squeeze all the seeds from the tomato into water and wash all the foreign matter from it; strain it through cheese cloth, and put out to dry. The seed will then be all separate from each other. How to Grow Vegetables.—One of the main essentials to get good cauliflowers is to have plenty of liquid manure, which, indeed, is most necessary in all the cabbage family. It can be applied once or twice a week to most vegetables. Perhaps a word on liquid manure may not be out of place. Take a carbide tin and cut the top out, then get an ordinary kerosine bucket and perforate it, putting in two double handfuls of lime, and filling with fowl manure.

Hang this in the carbide tin, and fill with water, and leave it for a few days before using. Bedroom slops added to the above makes it much better. If possible, always apply plain water before applying liquid. When transplanting any species it is always well to water with weak liquid manure. It is best for every gardener to grow his own young plants. The variety or strain you are the most successful with is generally the best to keep. To get early tomatoes plant your seed in tins cut down the side and bottom, tie round with string, make a hot bed of new stable manure, and cover with a frame of glass or logs. Put only two or three seeds in each tin, then, when large enough, remove tin and plant all out in beds. For each plant sink a hole about 18in. deep, fill with new stable manure, and plant on top. This causes heat and forces your plants along, and then becomes food for the roots as the plants develop. To get early fruit never water after the plant has got a start until the fruit is well developed. Pinch off the shoots just above the flowers. Insects, &c.—When planting out cabbage and all kindred plants dip them into some solution such as salty water, kerosine emulsion, or arsenate of lead. This will keep all grubs away until your plants have got a start. Ducks among the vegetables will remove grubs. To revive frost-bitten potatoes apply urine diluted with 1 to 12 parts of water. This will revive them wonderfully. For making liquid manure fowl manure is best, then pig, sheep, horse, and last cow manure. Always plant root crops on land that was manured the previous year. French beans grow remarkably on the heavy land west of Naracoorte. They must have an abundance of water. Never transplant onions on a windy day." Mr. W. H. Smith said the paper contained valuable hints. In growing French beans he always trenched them and flooded them twice a week with water. Mr. Rogers said that Mr. Haynes had referred to a small grub attacking vegetables. Mr. Hart, at the Millicent Branch, advised using a mixture of Paris green and bran—1lb. of Paris green to 1bush. of bran. The Chairman spoke upon deep working of soil for vegetables which were gross feeders, and advised growers not to over water. Messrs. C. Bray and A. Holmes also took part in the discussion.

**SHEEP AND WOOL.**—Mr. R. A. Jenkins gave an address on this subject. He said his experience of the small, fine-woolled sheep was confined to the short time he had resided in the South-East. He found that there were good fine-woolled sheep on the Hynam Estate, whence he obtained 300 flock ewes and some stud ewes to make a start. He mated them with Northern rams. He thought the big-framed sheep with shafty wool were too great a contrast to the small-framed Merino of the South-East, and therefore he got a half-bred of the Murray type. He mated them with 44 Hynam ewes, and the results were very satisfactory, so he went on with them. He came to the conclusion that was the line to follow. The Northern rams improved the frames of the Hynam type, and 2-teeth cut up to 26lbs. of wool. The wool was also a good type, and brought a good price. He did not believe in very wrinkley sheep, but favored what was known as "leather-necked" sheep. He had a few crossbreds for mutton, and they did remarkably well, but were rogues so far as feed was concerned. A neighbor of his went in for crossbreds, but he equalled him in weight of fleece, and obtained better prices—1d. to 1½d. per lb. on the average. He believed the Merino was the best for the country on the Hynam side of the range, but crossbreds would do better on the plains. At present crossbred wool was selling well, which was something in its favor. He did not favor the Lincoln cross. It produced too strong a wool with the Merino. The Romney Marsh and Leicester cross was the best for wool. He believed not many years would elapse before the farmers in their district would go in extensively for raising fat lambs. He believed in early lambs. A lot of South-Eastern people pinned their faith to lambings in May or June. They would have better lambs either in April or early in May. He had tried those periods, and had good lambs. However, they wanted their ewes in good condition to get good lambs, for they knew the old saying that half the breeding was in the feed. He was going to persevere with the experiment he was trying to get a larger framed Merino carrying more wool, but he admitted that he did not know where it would land him. So far he was satisfied. Last year the fleece of his wool brought an average of 1s. 0½d. per lb. He had brought a fleece of one of his

sheep with him to show how he classed his wool. The fleece was spread on a table and Mr. Jenkins gave an instructive lesson in classing. He deprecated using string in tying up fleeces. He showed the skin of a sheep, the progeny of the type he was raising on his farm, and explained the salient parts of the wool on the skin. The skin came off a large full-mouthed ram which Mr. Jenkins bred himself, and it had 2½ months' wool on it. He advised farmers if they wanted to get a larger framed sheep not to go in for a big ram with shafty wool, but to select a finer type, and stick to it until they obtained an even type. Mr. Jenkins, in reply to questions as to his mode of breeding the type of sheep he had in view, stated that when he used the first ram he had bred back on the daughters, mating a ram with them much of the same type as the old one. Mr. Feuerheerdts said breeding up to a certain type of sheep could only be done gradually. Mr. Holmes said Mr. Jenkins appeared to be on the right track, looking at his fleece and his skin. The Chairman (Mr. S. H. Schinckel) said the Naracoorte Estate had evolved a fine type of sheep from the fine Merino and the Murray strain of sheep. They were bred on the lines of Mr. Jenkins' experiments. He believed the success of the experiment was due to the late Mr. Chas. Coates, who managed the estate for some years. Messrs. W. H. Smith and W. Loller also spoke.

February 18th.—Present: 20 members.

VALUE OF A FARM ORCHARD.—Mr. Loller read the following paper on this subject:—"I think no farm complete without a small fruit and vegetable garden, and the two can be combined in one, for it will not hurt the fruit trees to grow vegetables between them. As a site for the garden I would choose, if possible, ground as near to the homestead as possible, sloping towards the east, as a protection from the south-west winds and for ease in watering the trees. I should also recommend a good breakwind a half a chain back from the garden. For the first year it is advisable to give it a good dressing with stable manure, a good ploughing, cultivating, &c. Then peas should be sown, and when in full bloom ploughed in. By this time the land is in order for the final working with the fruit tree plough, as deep as the land will allow, with a subsoiler fixed on it. This allows the roots to get well down without any obstruction. In planting, I like the square system. It is simple, and gives plenty of room to work between the trees. Trees should be planted 20ft. apart, with a good stake for each tree on the south-west side, to keep them upright. Cut away any torn or bruised roots. I like a well-balanced tree, fairly open, and not too high. Trees from the nursery should represent one year's growth. They should be cut right back to the height of the stem required, the laterals being cut back to the bare buds. An evenly balanced tree can be secured in the summer by just nipping the top out of the strong-growing shoots to help the weaker shoots. Any pruning done in the winter time tends to cause increased wood and leaf growth. When pruning is done in the summer it tends to produce fruit-bearing small wood. In wet districts it is best to plough once, and then put the scarifier through to keep the weeds down. Where matured trees are over-vigorous, and not fruiting well, they should be given less tillage and practically no winter pruning. The pests of the fruit tree are confined to the insect family and fungi. The insects are divided into two families—suckers and chewers. The former are got rid of by spraying them to kill by contact or smother them by blocking their air cells. The chewing or gnawing section can be destroyed by poisoning their food with arsenate of lead or other poisons. The fungus pests are either external or internal in their occurrence on the horticultural plant. The external kinds might be destroyed when their presence is seen by using dustings of sulphur or copper sprays. Those entering the tissues must be treated in a preventive fashion before their ravages are visible. This usually takes the form of spraying the trees with Bordeaux mixture or other copper compounds just as the flower buds are opening." Mr. Loller interspersed his paper with interesting explanations as he proceeded. In answer to questions he said he preferred pine trees as a break, as their branches came low, and gave better protection. Wattles and almonds are very good, but he advised that gums be not used, as they took too much out of the soil. He used Bordeaux mixture for spraying for shothole, and sometimes pure bluestone. In reply as to what were the best fruit trees to plant in a garden, he said that he had consulted Mr. Quinn,

the Government fruit expert, on the matter, and he had forwarded him a list of varieties, which he agreed with in most respects. The list was as follows:—  
**Apples.**—Early ripening—Gladstone, William's Favorite, Gravenstein, Ribston Pippin; medium—Jonathan, Dunn's Seedling; London Pippin, Dumelow's Seedling; long keeping—Rome Beauty, Stone Pippin, Rokewood. **Pears.**—Early ripening—Jargonelle; medium—Clapp's Favorite, William's Bon Chretien, Howell, Packham's Triumph, Beurre Capiaumont, Beurre Bosc, Madame Cole, Passans de Portugal, Vicar of Winkfield. **Peaches.**—Early—High's Early Canada, Triumph; medium—Wiggins, Mountain Rose, Elberta; late—Lady Palmerston, Salway, Pullar's Clingstone, Finlayson's seedling. **Apricots.**—Newcastle Early, Oullin's Early, Moorpark. **Nectarines.**—Dr. Chisholme, Early Rivers, Gold Mine, New Boy. **Plums.**—River's Early Prolific, Angelina Burdett, Early Orleans, Monarch, Greengage, Coe's Golden Drop, English Damson. **Japanese Plums.**—Wright's Early, Climax, Burbank, Wickson, Satsuma. **Quinces.**—Smyrna, Champion, Pineapple. **Table Grapes.**—Early (black)—Black Hamburg, Black Muscat Hamburg, Black Frontignac, Ulliade; (red), Red Frontignac, Red Malaga, Red Prince; (white) Early Green, Sweetwater, Crystal, Waltham Cross, Muscatel (Gordo Blanco), Belas Blanco, Doradillo.

April 10th.—Present: 21 members.

**POULTRY POINTS.**—Mr. F. A. Holmes read the following paper on "How to Judge the Points of Poultry for Egg-laying Purposes":—"We cannot fail to notice the improvement which has been made in recent years. In the earlier ages fowls were in a wild state, living in the forests and jungles, getting their living as best they could, and only laying sufficient eggs to bring out a clutch of chickens. Gradually they have been domesticated, and the breeds have been improved, and brought to the perfection of the present time. Perhaps owing to the laying competitions more than anything else do we owe the high standard which has been reached, and it necessarily commands our admiration at the results obtained. No authentic records can be found previous to the competitions, which are held yearly, and we can only conjecture that they were very low. The first records we can place any reliance on gives the average of 130 eggs per hen for the 12 months, which was considered good at that time; but the improvement has been so marked that at the last competition at Bendigo, Victoria, a pen of six White Leghorn pullets put up a score of 1,675 eggs, or an average of 279 eggs per bird. One can naturally conclude that the 300-egg hen will soon be an accomplished fact, showing to what a marvellous degree of reproduction they have been brought. By judicious selection and careful mating has this been brought about, and one has only to know the points of a good layer to attain such perfection. This experience is only to be gained by long study and acquaintance with the subject, although I admit that instances have occurred where breeders have jumped into fame after only a few years' acquaintance with the industry. **Breeds.**—Just a few words on the many breeds and varieties which go to make up the poultry world. First we have the Mediterranean, or non-sitting breeds, usually considered amongst the best layers, giving us a nice large white egg. Under this heading can be classed the Leghorns, Minorcas, Andalusians, Anconas, Hamburgs, and Spanish. The next class is what is commonly termed the dual-purpose fowl, suitable for egg farming and table purposes. Under this heading we have the Orpingtons, Rocks, Wyandottes, Langshans, Faverolles, Houdans, and Rhode Island Reds. All heavy breeds give brown-tinted eggs. Then we have the pure and simple table bird in the Brahmas, Cochins, Dorkings, and Game of all varieties. The balance of the breeds can be placed in the category of "fancy classes," and are practically useless for commercial purposes. In this we have Polish, Silkies, Sultanas, La Fleche, Red Caps, Crevecoeurs, and Bantams of many varieties. This classification may not be altogether perfect, but it will serve as a guide to speak upon. There are also other breeds which I have not enumerated. These different breeds mentioned have been used to make up other varieties, until under the heading of poultry we must have over 300 distinct varieties. For example, we take the Leghorn. In this we have the white, black, brown, blue, speckled, and pile varieties. Then

again the Wyandotte is represented by the silver, golden, white, blue, black, buff, partridge, buff laced, silver pencilled, columbian, and so on. From the Mediterranean or non-sitting breeds we get our best layers, and naturally it is from them that a breed has come to the fore and established itself as the one par excellence for producing eggs in large numbers. I refer to the White Leghorn, which has proved to be far ahead of any other breed for this particular purpose. Possibly this breed may have been selected and used to a greater extent than any other, yet the White Leghorn has always been admitted the best laying fowl in existence. The best layers are simply a matter of strain. This also relates to other breeds, which include heavy breeds such as Black Orpingtons, Silver Wyandottes, and others, having strains of heavy layers amongst them, which has been proved at the competitions. In heavy breeds, where the egg-laying has been developed to a high degree, there is usually a marked deterioration in type and feather, for, generally speaking, good layers of almost any breed are not true to type or feather, and they often deteriorate in size by inexperience through line breeding. Line breeding.—This is what some would term inbreeding; but, allowing this, it is done on scientific lines. If carried on with care it is the surest road to arrive at success. In selecting your stock birds every care must be taken, for on this depends success or failure. For preference, I would mate a one-year-old cock to two-year-old hens. You could mate any number up to 12; but, of course, if you have not that number of proved good layers, use what you have, and put in a few other hens which lay brown-tinted eggs. You can then easily pick out the white eggs of the Leghorns which you wish to set. From this progeny mate the most forward pullets back to their sire, which you would call No. 1 pen, and a good vigorous cockerel from the same progeny mated back with the hens would give you No. 2 pen. From these you would have the foundation and nucleus of a stud not too closely related to breed from, providing always that the stock intended to breed from would be both healthy, vigorous and carefully selected. Line breeding can only be practised successfully when both the male and female have no serious defects, for in line breeding, while you are intensifying the good points, you are at the same time intensifying the poor ones. Line breeding is a system that requires some skill, and considerable knowledge of what constitutes the good points in the stock bred. This goes to show that if it is to be taken up in the perfecting of a strain of birds—and no strain can be built up without it—it becomes a matter of the utmost importance to begin with as good stock birds as it is possible to procure, and free from any defects in body and constitution. When breeding chickens for almost any purpose, whether it is to improve your layers or for show purposes, or in any way to improve your stock, it is essential to have some identification mark, the same as is done by any stud sheepbreeder. For the purpose of marking poultry the most common method is to punch the web of the foot. Chickens can be marked with a special instrument (cost about 2s.) at a very early age. By this means something like 20 different marks can be made, and a record of same should be kept in a book for the purpose. You can therefore have complete control over your breeding stock, and consequently mate them as you determine: Egg-laying Points.—Now to come to our text, "How to judge the points for utility and egg-laying purposes." I take it by the word utility to mean that it is combined with egg laying, so I will deal with it from that aspect. It is an accepted fact that in poultry there is an egg-laying type and a meat type, judged by appearance, the same as there is a dairy and beef type in cattle. Signs sometimes fail, but it is generally believed that there is a definite type in poultry which indicates productiveness, the same as a good dairyman finds that certain characteristics and certain conformations of cattle indicate the productiveness or non-productiveness of certain individuals. The same general principles apply to the productive hen, and it is generally acknowledged that you can tell in a general way the good from the bad by certain and definite characteristics. For instance, a good layer stands high in front, and her back is not on a level, or the rear higher than the front. They usually have large combs, not heavy and beefy, but fine in texture, evenly and deeply serrated. They have a prominent, bright eye, set in a rather long, neat, and fine head. The body should be wedge-shaped, rather narrow in front, but wide behind and between the legs. There should be a great distance from the end of the breastbone to the end of

the pelvis bone. This indicates capacity and lots of room for egg production and digestive organs. The pelvis bones should also be widely separated. One special recommendation is to note the hens which leave the roost early in the morning, are always busy during the day, and late going to roost. Observation is one of the great aids in selecting good layers. Male Birds.—The type of male bird should in many characteristics be the same as the female, but whereas the comb of the latter hangs gracefully over the eye, the male's comb should be erect and set firmly on the head, and be deeply and evenly serrated with about five spikes. The plumage should be close or tight on the body, the tail full and abundant, and carried low. Avoid a high or squirrel-tailed bird. Always give preference to the noisy male, one that is constantly crowing and calling its mates. The male is the most important in the pen. His influence is equal to all the hens put together, because while each hen affects favorably or otherwise her own individual eggs, the male bird's influence affects every chicken that is hatched. Weakened vitality has been and still is one of the greatest elements in strain or breed degeneracy, and it requires a most diligent watch over your stock to detect it, as you may go on breeding from apparently strong and vigorous birds till the danger to your strain or breed is almost beyond repair. Always keep your male birds apart from the hens when you are not breeding from them. They give better fertility when mated up, and the progeny are more vigorous and healthy. Besides, you have infertile eggs, which keep much longer, and are undoubtedly better for table purposes. Also, never keep a lot of useless males, that only eat food which your laying hens should have. Dubbing, or cutting, the combs off your heavy-combed birds when not required for show purposes helps them very much. It is not cruel, and can be done by any novice. Simply take a sharp knife, or a pair of sharp sheep shears, and cut the comb off about half an inch from the head. Then take a few downy feathers from under the wing, and then apply a little Friar's balsam. It very quickly heals up. Now that feed is dear, get any green stuff (lucerne for preference) and put it through the chaffcutter, and feed it to the poultry in a trough or box. You will find it a great saving in your feed bill." Show Birds.—In reply to questions, Mr. Holmes explained the difference between the laying and show strains of fowls. He had dwelt chiefly with the Leghorn as being the best laying breed. The judges often dictated the kind of bird for show purposes by their awards. The judges favored a large Leghorn hen in shows, and it was generally accepted that very often the small hen was the best layer. His experience was that the smaller the hen the better the layer. The good layer had been obtained by inbreeding from good laying stock, and the inbreeding would account for the good layer being small. However, of late years the good layer and the successful bird at shows were approximating more in outward features, and by-and-by the successful show bird would be a fair-sized one, with the qualities of a good layer. Messrs. Moritz Brothers, of Kalangadoo, were in the foremost rank now in Adelaide with a good laying strain of Leghorns, and they were breeding a fair-sized hen. Judges would recognise the outlined features making for good layers, and there would not be any difference between the laying strain and the show strain. It would be a matter of time for this to come about, as breeders of show birds had to breed to suit the judges' taste. A discussion followed, the speakers including Messrs. W. H. Smith (Secretary), W. E. Rogers, W. Loller, W. G. Haynes, and J. M. Wray.

---

PENOLA (Average annual rainfall, 26.78in.).

February 13th.—Present: 11 members.

MAIZE.—Mr. Lampe asked whether it was possible to cure maize as hay, and at what stage to cut it. No member had had any experience in the matter. Mr. Miller said he always fed the maize green. He preferred broadcasting the seed on clay subsoil land in order to obtain finer stalks. He fed the maize to stock from January onwards. Mr. Kilsby had sown three plots. In the first the seed was broadcasted and ploughed under; in the second the seed was drilled in rows; and in the third the seed was cast on top of the ploughing and was then harrowed in and rolled. The third plot gave the best results. Mr. T. Ockley said he had drilled in 50 acres of fallow, sowing out of every fourth

hoe, making the rows 28in. apart. Round seed like Ninety-day maize ran well through the oat chutes, but larger seeded varieties, like Hickory King, required to be mixed with the fertilizer. The seed (11bush.), and the manure (7 bags of super.), were drilled in on November 2nd, 3rd, and 4th. The germination was uneven in some portions, and suggested that it was necessary to plough the land before the winter rains evaporated. By February 7th, the maize was green, vigorous, and ranged in length from 3ft. to 8ft.

GLENCOE, April 7th.—The various lectures at the recent South-Eastern Conference held at Mount Gambier were discussed. Messrs. J. Dow and G. F. Ferguson gave a resume of the lecture on "Forage Crops" delivered by the Director of Agriculture. Members agreed with Mr. Henshaw Jackson that the fleece from the Leicester-Merino cross was of better quality than that from the Lincoln-Merino. The individual weighing and testing of milk was considered too laborious except where dairying was conducted on a large scale.

KALANGADOO, March 13th.—The Hon. Secretary read a paper from *Elder's Weekly Review* on "Selecting Grain and Potatoes for Seed." A lengthy discussion followed on obtaining new varieties of potatoes for seed.

KALANGADOO, April 10th.—The delegates to the conference of the South-Eastern Branches, held at Mount Gambier in March, gave their reports. Mr. T. Bott thought more local matters should have been dealt with. The Director of Agriculture's lecture on forage crops was discussed. Mr. D. MacCorquindale favored maize for summer feed, and rye and oats, mixed, for winter use. The Secretary reported that he had met with success in the cultivation of rye and oats. If the two cereals were sown as a mixture with the first rains in March or April, good feed would be available in July, when it was most needed. He preferred peas for summer feed. Mr. W. J. Hemmings tabled nine fine Snowflake potatoes, grown from one stalk on swamp land. The proposal that the next South-Eastern conference should be held at Kalangadoo, was approved.

KYBYBOLITE, April 29th.—A scheme of co-operation, as outlined by the Clare branch, was not considered practical.

WIRREGA, April 3rd.—A paper previously given at Glencoe was read and discussed. It was decided that each member should conduct some experiments on a two-acre plot, under the supervision of the hon. secretary and chairman.

CLARENCE GOODE,

*Minister of Agriculture.*

## POINTS FOR PRODUCERS.

### District Conferences.

In conformity with the wishes of a large majority of the Branches included in the Pinnaroo and Brown's Well Lines Conference District, the Annual Conference will be held in the Tailm Bend Institute on Thursday, July 22nd. The sessions will commence at 3.30 p.m. and 7.30 p.m. The opening address will be delivered by the Minister of Agriculture (Hon. C. Goode, M.P.), and in addition to papers to be read by delegates from Branches, addresses will be delivered by the officers of the Department of Agriculture. Local arrangements are in the hands of the Wynarka Branch.

The Eyre's Peninsula Branches' Conference will be held at Cowell on August 3rd, arrangements being in the hands of a local committee, of which Mr. H. P. McCallum, of Carpa, is Hon. Secretary.

### Stock Diseases.

In order to prevent any confusion in the minds of stock owners as to their responsibility under the provisions of the Stock Diseases Act, attention is drawn to the following diseases which have been proclaimed as notifiable:—Actinomycosis, anthrax, cancer, catarrh, dourine (or equine syphilis), equine fever, epizootic lymphangitis, farcy, foot and mouth disease, glanders, lice, pants (or contagious pneumonia affecting swine), pleuro-pneumonia, rabies, rinderpest, scab, sheep pox, surra, swine fever, tick fever, trichinosis, tuberculosis. All suspected cases of any of the above diseases should be immediately reported to the Chief Inspector of Stock, Adelaide. Request for advice on stock complaints, not suspected of being contagious, and other veterinary advice through the medium of the *Journal of Agriculture*, should be addressed to the "Editor." This course is advised as letters or telegrams addressed to the Government Veterinary Lecturer, either by name or title, may be left unattended for several days, whilst that officer is away in the country.

### Field Trials.

The value of a competitive trial in the field of agricultural implements has long been realised; the advantage of seeing farm implements actually at work under local conditions being one that appeals to farmers. Manufacturers, too, have fully realised the excellent means of advertising which are thus afforded, and the Railways Commissioner provides for the free back carriage of implements sub-

mitted for trial and remaining unsold. The Northern Yorke's Peninsula Field Trial and Show Society, which is affiliated with all of the Branches of the Agricultural Bureau in the particular district in question, has taken active interest in demonstrations of this nature. This body has arranged for an exhibition to be held at the farm of Mr. W. M. Brown, situated about two miles west of the Melton Railway Station, on August 25th, at which it is anticipated officers of the Department of Agriculture and members of the Advisory Board of Agriculture will be present, in addition to the general public.

### Changing the Feed.

The following particulars, of considerable interest to owners of livestock, were supplied by the Director of Agriculture (Professor Arthur J. Perkins) to a correspondent, who stated that hitherto his horses had been fed on wheaten hay chaff and bran; he desired to include barley in the ration, leading up to the grain feeding gradually. "Assuming," said Professor Perkins, "that your horses weigh 1,500lbs., or thereabouts, and that you wish to use a ration of 15lbs. wheaten chaff, 12lbs. crushed barley, 10lbs. bran, I would suggest that you lead up to the full ration as follows:—

|                      | First<br>Week. | Second<br>Week. | Third<br>Week. | Fourth<br>Week. |
|----------------------|----------------|-----------------|----------------|-----------------|
|                      | lbs.           | lbs.            | lbs.           | lbs.            |
| Wheaten chaff .....  | 35             | 28              | 21             | 15              |
| Crushed barley ..... | 3              | 6               | 9              | 12              |
| Bran .....           | 10             | 10              | 10             | 10              |

### The Ration for the Milch Cow.

The ration for a cow in milk will depend on her size and on the quantity of milk she is yielding. I indicate below (says the Director of Agriculture) standard rations for cows weighing 1,000lbs. (average crossbred) and 750lbs. (Jersey) for yields of 40lbs., 30lbs., 20lbs., and 10lbs. respectively.

#### 1,000lb. Cow.

|                      | lbs. | lbs.     | lbs.    | lbs.    |
|----------------------|------|----------|---------|---------|
| Milk yield .....     | 40   | 30       | 20      | 10      |
| Wheaten chaff .....  | 9    | 8        | 9       | 8       |
| Lucerne hay .....    | 15   | 14       | 10      | 7       |
| Bran .....           | 12   | 9        | 4       | 2       |
| Crushed barley ..... | 5    | 4        | 5       | 4       |
| Present value .....  | 4s.  | 3s. 4½d. | 2s. 9d. | 2s. 1d. |

#### 750lb. Cow.

|                      | lbs.      | lbs.     | lbs.    | lbs.     |
|----------------------|-----------|----------|---------|----------|
| Milk yield .....     | 40        | 30       | 20      | 10       |
| Wheaten chaff .....  | 7         | 6        | 7       | 5        |
| Lucerne hay .....    | 10        | 10       | 7       | 5        |
| Bran .....           | 9         | 7        | 3       | 2        |
| Crushed barley ..... | 4         | 3        | 4       | 3        |
| Present value .....  | 2s. 11½d. | 2s. 6½d. | 2s. 1d. | 1s. 7½d. |

### Feeding Pickled Grain to Stock.

"Bluestone, like all copper salts, is poisonous in character, and it is not wise to feed pickled oats to horses. Horses, indeed, are more delicate in this direction than the other domesticated animals. Bluestone, however, is soluble in water, and if the oats are washed in running water, or in several changes of water, it is probable that the great bulk of the pickle will be removed."—Professor Perkins.

### Prickly Pear for Stock Feed.

In order to determine the possibility of using prickly pear (*Opuntia*) as fodder during times of famine, some feeding experiments were carried out at the Government Civil Dairy, Kirdee. Six bullocks were fed with a mixture of 100 parts of prickly pear to six parts of cotton seed at the rate of 72lbs. per 1,000lbs. live weight per day for six months. The prickly pear was prepared for consumption by first burning off the spines over a stove, and then cutting the slabs into small pieces by means of a chaffcutter or a chopper. The burning was accomplished at various rates, from 30lbs. to 100lbs. per hour according to the stove used. The composition of the prickly pear fodder was as follows:—

|                     | Dry Season.<br>Per cent. | Wet Season<br>Per cent. |
|---------------------|--------------------------|-------------------------|
| Moisture .....      | 79.32                    | 92.75                   |
| Ether Extract.....  | 0.78                     | 0.22                    |
| Albuminoids .....   | 0.68                     | 0.31                    |
| Carbohydrates ..... | 11.61                    | 4.37                    |
| Fibre .....         | 2.48                     | 0.85                    |
| Ash .....           | 5.13                     | 1.60                    |

The animals were in very poor condition at the beginning of the trial, and all improved markedly as time went on; four out of the six took the ration readily from the first, while the other two were longer in getting accustomed to it. The fodder was also fed successfully to a mixed dairy herd of cows and buffaloes in quantities up to 14lbs. per head per day, and to young stock. Altogether, as a result of the trials, it may be said that the mixture of prickly pear and cotton seed used will not only support life but enable an animal to regain condition even after it has become very poor from semi-starvation.—*International Institute of Agriculture Bulletin.*

## INQUIRY DEPARTMENT.

Any questions relating to methods of agriculture, horticulture, viticulture, dairying, &c., diseases of stock and poultry, insect and fungoid pests, the export of produce, and similar subjects, will be referred to the Government experts, and replies will be published in these pages for the benefit of producers generally. The name and address of the inquirer must accompany each question. Inquiries received from the question-boxes established by Branches of the Agricultural Bureau will be similarly dealt with. All correspondence should be addressed to "The Editor, *The Journal of Agriculture*, Adelaide."

## STOCK INQUIRIES.

Replies by Mr. F. E. PLACE, B.V.Sc., M.R.C.V.S., Veterinary Lecturer.

"J. S., sen.," Steelton, has a mare 15 years, which just mopes round and fades away.

Reply—A very common complaint in these days, but as she has been drenched, there is a risk of mechanical pneumonia existing. Feed on green or soft food and give a teaspoonful of Fowler's solution of arsenic on the tongue with a little molasses three times a day for a week or 10 days.

A member of the Hartley Branch asks for a description of the symptoms of a mare about to slip a foal.

Reply—As a rule at six months there are no symptoms. The mare simply gets rid of the foal, and afterwards falls away on account of the fever. If there are symptoms there is pain, stretching out, whisking tail, discharge from bearing, and sometimes flush of milk. After the accident, a few doses of aconite alternated with 10-drop doses of pulsatilla will improve matters.

"W. P. F.," Willowie, has a gelding which suffers from gripes, and scours, then gets bogged, seems strained, and swells about the pizzle and under belly.

Reply—Bloodworms; for full treatment see May issue of the *Journal*. Slinging may be necessary in this case.

"M. M. C.," Redhill, has a mare, 7 years, with a swelling behind the jaw in the jugular furrow.

Reply—Probably glandular; if rubbed daily with a bit of blue mercurial ointment as big as a nut swelling will probably disappear. Better effect will result if warm water is well applied first. A week's treatment should suffice.

"D. J. D.," Long Plain, has a light colt, three years, which fell on stony ground while being broken in, and cut the outside of fetlock. He seemed to be getting on all right, but after a few weeks could not put his foot to the ground. Three months later the fetlock was healed, but was still very stiff, hard, and about double the usual size.

Reply—Most probably there was a partial fracture, which later became complete, and as time went on a large callus formed. Treatment is not at all likely to be successful, and if the colt is valuable it would be better to call in a qualified veterinary surgeon. If home treatment is decided on, plaster the joint with warm pitch and Stockholm tar in equal quantities, putting on dabs of wool while it is warm (not hot), and making a plaster half an inch or more thick all round the joint, and leaving it on for months until it wears off. A blister is not advisable until seen by a veterinary surgeon.

"B. B. R.," Truro, reports the death of a mare which suffered from loss of appetite and strength, especially of the hind quarters. She was killed, and the small bowels were found to be stuffed with hundreds of white worms up to 8in. or 9in. long, tapered at both ends, which had not eaten into the bowel.

Reply—The worms are the common round worm of the horse (*Ascaris megalocephala*). They just live in the small bowel and rob the horse of nutriment. In addition they eliminate poison (tænia toxin), which produces the symptoms. They are very common in the district named. Treatment should be a brisk purge to start with. For a two-year-old or under give  $\frac{1}{2}$  pint of castor oil and a like quantity of warm milk; and for two or over a 6-dram aloes ball or a pint and a half of raw linseed and castor oils mixed and two tablespoons of turpentine added. Afterwards worm powders such as are often prescribed in the *Journal* may be given. Arsenic is not of much avail for these worms, which do not like healthy green feed, this latter being the best remedy for them.

"C. B.," Penola, describes the sufferings of a mare which pined away and died. He forwards some worms.

Reply—The worms sent, although they look like flukes, are an ordinary tapeworm of the horse, and have the somewhat alarming name of *Anaplocephala mamillana*. They are common in the South-East of this State, and indicate poverty of condition and feed, as strong healthy horses generally manage to get rid of them when

there is green feed. It is highly probable that there were other kinds of worms at work, but so microscopic that they would pass unnoticed. In similar cases a purge of half a pint of castor oil, with a like quantity of warm milk, followed by a course of Fowler's solution of arsenic will generally be found effective.

"F. W. A.," Strathalbyn, has a cow which puts her head round to the root of the tail, then straightens out, gets giddy, and falls, but does not seem to suffer in condition or milk.

Reply—The symptoms are those of diseases of the meninges or coverings of the brain. The two most likely to be involved in this case are tuberculosis or yacca poisoning, so that it would be well to ask the Deputy Chief Inspector of Stock, Mount Barker, to see her. If he decides that it is not tuberculosis, which the condition seems to eliminate, then she could have twice a day as a drench in a pint of warm water or as a powder mixed in her food, one teaspoonful each of powdered nux vomica, sulphate of quinine, sulphate of iron, sulphur and sugar. If after a few days' treatment she improved, it could be kept up for two or three weeks with advantage.

"J. J.," Ramco, has a gelding, seven years, with good teeth, which slobbers enough to swamp his manger, eats enough for two horses, never looks well, and swells at the sheath and hind legs. The swelling goes off after the animal is worked for an hour or two.

Reply—Arsenic will not be the best drug for him, although it would do good, but a heaped teaspoonful of baking soda in his feed twice a day for three or four weeks will probably improve matters. His trouble arises from stomach abscesses caused by very minute worms enjoying the name of *Habronema equi*, which like an acid surrounding. The soda renders them weak and unable to breed. However, if the abscesses are already large, which is probably the case, he may be found dead one morning, or give a day or two's trouble, and after sitting up like a cat with food gushing from his mouth and nose, will die.

"W.S.C.," Two Wells, has a colt which was castrated by emasculator in very cold weather; swelled much and went very mopey; ate very little; did not lie down, and eventually died.

Reply—The emasculator was not in itself to blame, but apparently peritonitis ensued, possibly the colt had bloodworms; an occasional accident of this sort will happen in the best of regulated farms.

"L.H.," Langhorne's Creek, asks if cactus (prickly pear), is of food value to stock.

Reply—Prickly pear denuded of thorns has a feeding value for stock nearly equivalent to turnips. If, however, the thorns are not

thoroughly removed by roasting or otherwise they are a danger to the stock feeding on them, and the labor of removing them is more than the worth of the feed obtained.

A horse belonging to "C.D.," Belalie North, will not eat or drink, stands about and lies flat; pain at first, not at present.

Reply—Very probably sand. Give a pint of new milk with a pound of honey warmed up in it as a drench, and tempt with a little green food. The prospect of recovery is not bright, as probably worms have injured the coats of the bowel and blood vessels as well.

"A.J.R.C.," Cleve, has a 2½-year-old colt, which has a ravenous appetite, harsh coat, feeds wolfishly, and spits out, with difficulty in swallowing.

Reply—Teething and worms. Give half a pint of castor oil, with a similar amount of warm milk. Examine the back teeth, and remove the crowns of temporary molars from the permanent ones being pushed up. Give every day for a fortnight as much grey powder as will lie upon a sixpence in a little bran and green food by preference. The pronunciation of hæmorrhagic is hem'-orajik; it means "pertaining to blood" or "blood flow."

"A.T.," Cleve, had a 5-year-old mare which swelled and died before treatment could be given; there was stoppage in gut of half-chewed grass and straw.

Reply—The change on to green feed caused too rapid fermentation of bowel contents, otherwise there might have been a chance for the calculus to be broken up by the natural movement of the bowel. Had treatment been available a stimulant with peppermint might have been of use.

"G.E.," Mildura, asks (a) treatment for serious abscesses on shoulder; (b) cocaine anæsthesia; (c) treatment for swollen cord.

Replies—(a) make a bold incision at the lower end of back of abscess, evacuate contents, paint inside thoroughly with iodine, stop work during treatment; (b) one grain of cocaine hydrochlorate dissolved in 30 minims of camphorated water, will give about half an hour's anæsthesia, allowing five minutes for absorption. This suffices for all ordinary operations; (c) one dram iodide of potassium twice daily in a little bran till hair begins to fall off (about a fortnight) no local treatment.

"E.A.J.," Manoora, has a horse which throws up his head when drinking, staggers as though he would fall, but keeps condition on heavy work.

Reply—The symptoms are those of stomach worms (*Habronema equi*), and bots. The treatment for the latter has been fully des-

cribed in previous issues. The former may be treated with improvement by giving a heaped teaspoonful of baking soda in the feed twice a day for a month or so.

"A.A.G.," Lameroo, had a horse which died after colic; *post-mortem*, nothing much was found wrong with bowels, but the big blood vessel down the back (*aorta*), was full of jelly-like fat.

Reply—Microscopic blood worms were the trouble, and a clot from the blood vessel caused the heart distress noticeable; at the attack it was too late to have cured the horse, but earlier Fowler's solution of arsenic would have been of use, as described in *Journal*. The fat substance is known as a *verminous thrombus*.

Parrakie Branch Agricultural Bureau submit a number of questions:—(1) Treatment for a filly, rising three years, with swelling as large as a fist on point of shoulder; this becomes harder with work.

Reply—A serous abscess; foment well with hot water with a lump of washing soda in it, and then make a slit 2in. long at the bottom of the back of the swelling, when some fluid will escape, and on putting the fingers in, a thickening will be felt. This is the fluid organising into fibrous tissue. Make a swab of cotton wool or rag, dip it in spirit of iodine, and thoroughly swab out the cavity; do this daily for a few days, giving the mare light work at the same time, as the pressure will help to evacuate the contents of the cyst through the hole at the back. This may be left to heal with a few dressings of the spirit of iodine.

2. A colt was cut above the hoof with barbed wire; the wounds have healed, but have left a thickening. Can this be reduced.

Reply—It is impossible to say whether this will be permanent or not without handling the colt, but it will be well to try rubbing in a little blue mercurial ointment, the size of a nut, into the swellings every day for a fortnight or so, and then waiting a few months to see if they are absorbed; if not, apply again for further advice.

3. Is any advantage gained by mixing Fowler's solution of arsenic with water, in order to secure a distribution of the drug through the chaff.

Reply—There is neither advantage nor disadvantage in diluting the Fowler's solution as suggested; the writer generally gives it neat, as mixed on top of the feed, it is readily taken in the first few mouthfuls. With regard to price, the chemists put up a cheap veterinary form which is obtainable from 1s. to 2s. 6d. a pound in Adelaide; this makes it a very cheap drug to use.

"T.B.," Carrow, reports that a cow has been violently galloped by a person on horseback, apparently through or over a fence. It is five

months gone in calf, gives bloody milk from front offside teat, has small lump at head of teat; the milk yielded is stringy. He asks whether the animal will lose its teat.

Reply—First, galloping is not advisable; this is putting it mildly. Second, there is mammitis or inflammation of the structure of the gland, and it is quite possible that she may lose her quarter. Thirdly, foment well with thick and hot soapsuds two or three times a day, then rub in some of a mixture made of loz. tincture arnica,  $\frac{1}{2}$  pint glycerine,  $\frac{1}{2}$  pint methylated spirit. Always strip well, and once a day for a few days after stripping inject up the teat two tablepoons of the same mixture. If the teat seems to be going blind keep it open with a milk syphon, but carefully boil this both before and after use.

“H.C.U.,” Bowmans, reports that a cow slipped calf at about five months, was found next morning with breeding bag out and cleaning attached. This was washed in lysol and warm water, but the after-birth seemed to be attached to growths of the womb, some of which separated. The cow was shot.

Reply—In the cow, the cleaning or foetal membranes are connected with the womb by about two dozen eminences or growths called cotyledons, and in these the blood vessels of the dam interweave with those of the young. After birth the cotyledons separate, and the half remaining on the lining of the womb gradually withers away or atrophies. The growths were cotyledons. As the birth was premature they were not in a condition to separate, hence the trouble, but they had nothing to do with the slipping calf. Nothing could be of service to the cow until the womb had been replaced, as described in a lecture at Balaklava, and then a quart of strong coffee would have been the best thing for her. The fact that her previous calves were small was partly accounted for by her breed, as Herefords seem to have small calves, which grow rapidly after a few weeks.

A correspondent forwards a 4-in. wire nail which had been imbedded  $2\frac{1}{2}$  in. in a horse's foot for six weeks before it was noticed and taken out. The foot festered. He inquires, “What is to be done to remove the matter and heal it up.”

Reply—Six weeks, and foot not looked at, does not speak well for the owner's horsemastership. Wash the wound with hot water with a good lump of washing soda in it; then see that there is a good drainage, paint with spirits of iodine (composition of which see practically every number of the *Journal of Agriculture*), do this every day till the wound looks like healing, then plaster with Stockholm tar, and leave to Nature, and do not blame Providence if lockjaw sets in.

"F.H.K.," Undalya, has a horse, the eye of which has been injured by barbed wire, removed; but matter comes from nostril and near eye, where is swelling.

Reply—The trouble is either a growth of a cancerous nature or there is damaged bone. As cancer is notifiable under the Stock Diseases Act, it is necessary for you to report the case to the Chief Inspector of Stock, Adelaide, who will send an officer to investigate. Failure to report involves a heavy penalty. If the Stock Department decides that it is not cancer, treatment can be carried out as the officer will direct.

"M.L.H.," Naturi, had a cow suffering from dry bible. Treatment with saltpetre, bone meal, and phosphate of iron had effected improvement, but the animal's toes grew enormously.

Reply—Continue the bone meal and saltpetre, and if the syrup of phosphate of iron is not too expensive, that also; but benefit will be derived by giving her once a week or so a pint of yeast in a pound of molasses and a pint of milk, if available; otherwise water. Yeast prepared from dry yeast cakes will do, but if not obtainable, a pound of currants may be substituted. There is a very fair prospect of recovery. The over-growth of the toes is very typical of the disease, which is near akin to scurvy in human beings; the toes should be cut. Treatment will not be prolonged as the green stuff comes along.

"L.W.D.," Hahndorf, has a colt with enormously swollen testicles. He asks treatment.

Reply—Without seeing the colt it is impossible to say whether the condition is scrotal hernia or sarcocele. In either case foment the enlarged scrotum well two or three times a day and sling the part in a bran bag tied over the loins to relieve the weight. Twice a day mix with a spoonful of molasses as much iodide of potassium as will lie on a sixpence and put in his mouth for ten or fourteen days, and then report progress.

"F.T.S.," Victor Harbor, has a four-year-old horse which has had a dry cough for about eight months, principally whilst feeding and after drinking.

Reply—Of no serious importance; the cough arises from the cutting of the last four molar teeth, and will disappear when they are up. It may be relieved by mixing equal parts of honey, glycerine, and lemon juice, dipping a rag in the mixture and tying round the bit and leaving it in the mouth for an hour or two a day. Work as usual.

"P.B.," Port Augusta, asks for treatment for a horse affected with boils under the collar.

Reply—The long continuance of dry feed has something to do with the appearance of these boils, which are enlarged glands under the skin, which burst and run together, making nasty sores. Give a tablespoonful of sulphur in the feed once a day for a week or 10 days. Take particular care to beat the collar out with a billet or bottle every evening, and if very sweaty, dry by fire. Groom the shoulders of each horse both on leaving work and before commencing. Either chamber the collar or pad it so that there is no direct pressure or friction on the sores, and then work reasonably. Foment the shoulders after work with hot water with a lump of washing soda in it, so as to encourage the boils to burst; after drying with brisk rubbing, dress with a mixture of tr. arnica 1oz. and methylated spirit 1 pint. Also mix 2oz. of white lead in a pint of neatsfoot oil and dress the swellings or sores with it before work midday and evening. The police are justified in stopping a horse with these boils if the collar is rubbing; if it is not they will not interfere.

"W.F.," Taplan, has a five-year-old gelding which breathes heavily, has a cough, very hollow in flanks, off feed, and frequently passes water; after being drenched with raw linseed oil some returned through nostrils.

Reply—The drench has gone the wrong way, and inflammation of the lungs has set in; he may be dead before the reply arrives. In any case little can be done. Give 10 drops of veterinary arsenicum on tongue three times a day, if improving.

"E.L.," Custon, forwarded a piece of the lung and entrail of a draught mare; treated for worms, and drenched with raw linseed oil and turps.

Reply—The lung was inflamed, the bowels also, on account of migrations of microscopic worms invisible to naked eye. It is to be feared that some of the oil and turpentine went the wrong way.

"S.H.," Gawler, has a cow in good condition; within six weeks of calving became paralysed in the hind quarters, but had no pain, and recovered towards evening.

Reply—The symptoms are produced by a kind of lumbago, and it is well to rub the loins with liniment (see "Medicine Shelf," August, 1914, *Journal of Agriculture*), 10 drops of vet. tr. rhus. tox. twice a day, for a few days help. When the attack comes on closer to calving it is not usual for the cow to get up before that is over. The bowels should be kept loose; molasses in feed will do this.

"J.G.," Clare, has been giving poor horses 4 grains of arsenic once a day in the feed for a fortnight. They are improving in condition.

He asks a safe dose of arsenic for a horse, and whether crude arsenic might accumulate inside the animal, with harmful effects.

Reply—A safe dose of arsenic for a horse given daily for two or three weeks is the quantity you mention, but the chemist is right in saying that sometimes there is a cumulative effect, so that the four grains is better given in the form of Fowler's solution, as that preparation is more completely and rapidly absorbed than crude arsenic, and it is much easier to measure two tablespoonfuls than four grains. Most chemists sell Fowler's solution so cheaply that there is no monetary advantage in using the crude drug, with which accidents do occur sometimes.

"W.R.W.," Wilkawatt, has a horse which is easily knocked up. Had a pint of raw linseed oil and two tablespoons of turps; next day would not eat, lay on side kicking for two days, then appetite returned; then got worse, and stuff like contents of water gut came through nose.

Reply—The symptoms well described point to a partial rupture of the wall of the stomach, which was the case, the specimen sent being an abscess resulting from invasion of minute worms called *Habronema equi*, which spend their early life in flies. They are generally present when a horse slobbers, in which case their activities can be lessened by giving a teaspoonful of baking soda once or twice a day for a few weeks.

"R.H.," Currency Creek, reports the loss of three cows; on opening *post mortem* the bibles were found packed with sand.

Reply—Probably from drinking sandy water. It is difficult to get the sand out of the bible, but 10 drops vet. tr. nux vomica twice a day and 10 drops vet. tr. byronia twice a day for a week or 10 days will help, as will grooming the cows' flanks for a few minutes twice a day. Feed a pound or two of molasses for a few days as well.

"J.W.," Warnertown, has a mare running on good wheat feed, which is putting on condition, but breathes short.

Reply—There are many reasons for the short breathing, but the most likely is that she has caught a cold. Try a rag dipped in Stockholm tar wrapped round the bit for an hour or two a day for a week or so. Glad to hear the horse with bloodworms is on the way to recovery, as the "Result" line in the case book can be filled up instead of being left blank, as it so often has to be.

"W.O.," Wasleys, has a horse which was cut in front of hock with smooth wire, continues to discharge in spite of antiseptic treatment.

Reply—The discharge is probably from an injured oil sac, and improvement will follow the daily application of a pinch of chloride of

lime (bleaching powder) to the spot. Dress the rest of the wound once or twice a day with spirit of iodine (see *Journal of Agriculture*, August, 1914).

“F.M.H.,” Bletchley, asks that a stallion should be examined, and a ration for such an animal.

Reply—The examination and certification of stallions is carried out by the veterinary officers of the Stock and Brands Department, and application should be made to the Chief Inspector of Stock, Adelaide, who will advise arrangements. The Veterinary Lecturer does not make private visits. A good ration to get the stallion into hard working condition, which is far better than the blubber one sees on most, would be daily:—Wheaten chaff 30lbs., long hay 10lbs., oats 8lbs. to 10lbs., bran 3lbs. If peas are available, the smaller oat ration and 2lb. peas;  $\frac{1}{4}$ lb. boiled linseed will help the coat, and may be mixed with the oats, bran, and chaff. Give plenty of exercise, preferably in the form of light work.

“M.L.,” Hornsdale, has a four-year-old horse blind, the eyes being large, protruding, and glassy.

Reply—The condition is known as amaurosis, and is caused by an alteration in the circulation of the brain and paralysis of the optic nerve; as a rule it is permanent, and the horse gradually becomes used to his infirmity; sometimes, however, the sight is restored by removal of the pressure as the horse gets older; this is possible in a four-year old. Give 10 drops of vet. tr. belladonna once a day for a month and kindly report if any change. The medicine is just put on the tongue or teeth with a smear of molasses.

“M.L.,” ———, reports that his horses lie down, some stretch out, some have pain, and all are reluctant to rise.

Reply—The symptoms are those of irritation in the large bowels, which are probably caused by sand and possibly bloodworms. For the treatment of either or both refer to recent numbers of the *Journal of Agriculture*.

“J.W.S.,” Willalo, lost two cows; they staggered, fell, swelled, and then expired.

Reply—Luscious green feed produces these symptoms, owing to the very rapid evolution of poisonous gases in the paunch; the darkness of the blood is due to the same reason. Treatment—Stab in the highest part of the swollen paunch on the left side; this corresponds to the middle of the V of the flank when hollow. Drive the knife well in, and give it a half turn, letting it remain in till the gas has escaped. In less acute cases, tie a stick about a foot long and an inch in diameter

in the mouth like a bit, and move the cow around briskly; this causes the gas to come up. Give a pint of warm milk and a pound of molasses. Never let cows out on wet green feed till they have had a full feed of straw or similar feed, so that they will not gorge too rapidly.

“E.J.H.,” Coonalpyn, reports that a mare, rising 5 years, trembles occasionally, but eats and drinks well. Has been treating it for blood-worms.

Reply—Probably dietetic trouble. Give a little ( $\frac{1}{4}$  pint) yeast in feed daily, and continue worm treatment, if not giving santonine, as this drug would produce trembling. Add oats and, if possible, peas or peameal to feed.

#### WEEDY LAMBS.

Replies supplied by the Director of Agriculture (Professor  
ARTHUR J. PERKINS).

A member of the Salt Creek Branch of the Agricultural Bureau reported that a number of his lambs this year were weedy; and quite a number of the ewes bore twins. He had had the sire for five years, and asked whether the above could be attributed to this fact. He also asked the length of time a ram could be kept in a flock without the flock degenerating.

Replies—As a breeding animal a five-year-old ram is quite good, if its teeth are still in good condition, as they should be. The weediness of the lambs will probably be due to the hard conditions the dams had to put up with last year; carrying twins would only aggravate the condition. It would be better to knock one on the head. A ram may be retained as long as his teeth hold out; degeneracy is not likely to arise from age; in-breeding might account for it, if the ram is mated with his descendants. The only disadvantage of an old but healthy ram is that he becomes lazy.

#### AGRICULTURE.

An inquirer from Sherlock asks the size of the mesh required to be used for grading seed wheat.

Reply—The sieves in common use for separating grains are usually measured in millimetres; and for the cereals they usually commence at 2.00 millimetres and then increase as 2.25, 2.50, 2.75, 3.00, and so on. These measurements are for rectangular holes, which, as a rule, are at least three times as long as broad; the measurements of course are for the width. The sizes of the different varieties vary considerably, and to meet this you should at least have, for accurate work, three sieves, as 2.25mm., 2.50mm., and 2.75mm. For your pur-

pose I think the middle size, i.e., 2.50mm., will be all that is necessary; it might let a little too much through of varieties with small grain, like Comeback, for instance, but with the majority of our wheats it will only remove broken and shrivelled grains.

Replies supplied by Mr. W. J. SPAFFORD, Superintendent of Experimental Work.

“A.V.,” Salt Creek, asks—(1) How sorghum should be sown? (2) Will the pickling of wheat containing smut balls cause spores to germinate before the seed is placed in the soil?

Replies—(1) Sorghum should be sown in rows wide enough apart to allow room for cultivation with a horse hoe. This is quite essential in the “dry” areas, in order to conserve the moisture. It is equally necessary where the crop is irrigated, to run the water between the rows. The sowing is best done through the manure side of the drill by mixing the seed with the fertiliser (preferably bonedust), and only running it through every third hoe. (2) The “pickle” used on wheat containing “bunt” does not germinate the spores. It acts directly on them, killing all with which it comes in contact. Should the moisture in the “pickle” germinate the fungus, it will only live until it meets some of the solution, or, failing to reach the solution, until the wheat becomes dry.

#### PLANTS, WEEDS, &c.

Replies supplied by Professor T. G. OSBORN, D.Sc.

“P.A.,” Halbury, forwarded a specimen of a plant for identification and expression of opinion as to its possession of poisonous qualities.

Reply—Identified as *Euphorbia drummondii*, which, though often suspected of being poisonous, has been proved to be harmless. It is suggested that it may cause ill effects in two ways—(1) by its juiciness if eaten in quantity by starving stock; or (2) in that it may contain a ferment capable of freeing hydrocyanic acid from other plants containing a cyanogenetic glucoside. It is useless as a fodder plant.

#### HEATED SUPERPHOSPHATE.

The Crystal Brook Branch of the Agricultural Bureau asked whether the quality of super. would be impaired through subjection to heat, such as would be caused by the burning of a shed in which it was stored.

The Government Analyst (Mr. W. H. Hargreaves, M.A.) replies—If the super. became strongly heated it would lose moisture, and also water of composition, and be converted into a meta or pyro-phosphate.

If the heat was not sufficient it might still be hot enough to cause some reversion to dicalcic phosphate owing to the fact that superphosphate is always damp, and contains water, which on boiling, would probably cause reversion. If the super. was closely stacked in a shed it is highly probable that the shed could be burnt down without affecting the super., except on the surface.

### HORTICULTURE.

Replies supplied by the Horticultural Instructor (MR. GEO. QUINN).

"Rome Beauty," Scott's Creek, inquires:—(1) Whether winter spraying of apples and pears is advisable; (2) best spray to use; and (3) whether certain advertised sprays are efficacious.

Reply—(1) In districts such as yours, spraying during the early winter is valuable when used both against insect and fungus pests; (2) The best known combination which is both insecticidal and fungicidal in its action is the lime-sulphur spray, but of course it can scarcely be expected to destroy all kinds of insects or fungi. (3) The spraying oils mentioned may be confidently recommended for use during the dormant season of deciduous trees, and as a remedy against woolly aphis, mussel scale, and red spider (or *Bryobia*) are worthy of trial. There is no substantial evidence supporting them as fungicides. In respect to the general question of winter spraying, I think the use of lime-sulphur should prove valuable to you, as it is highly recommended in other States for use against red spider, and as a fungicide, but we cannot state whether it will kill woolly aphis or mussel scale. Lime-sulphur is made by boiling fresh lime and sulphur together in the proportions of 1lb. of fresh lime and 2lbs. sulphur to each gallon of water, and then diluting to seven gallons for spraying; but as the home-made article is variable in composition some of the concentrated forms prepared on more exact lines and obtainable from local seedsmen and dealers are to be preferred.

## WHAT THE MAN ON THE LAND WANTS TO KNOW.

Address by the Director of Agriculture (PROF. ARTHUR J. PERKINS), at Inman Valley.

The Director of Agriculture (Prof. Arthur J. Perkins), accompanied by the Dairy Expert (Mr. P. H. Suter), attended a meeting of the Inman Valley Branch of the Agricultural Bureau on May 26th. The Chairman (Mr. H. J. Jagger) formally welcomed the visitors, who, by request, delivered instructive addresses and answered many pertinent questions. The guests were heartily thanked by Mr. H. J. Meyer, and the Director in reply stated that he and his colleagues on the staff of the Department of Agriculture were always ready to help the members of any Branch in overcoming difficulties in practice and in seeking the solution of problems connected with the effective occupation of the land.

The Director's address took the form of comprehensive replies to a series of questions submitted by members. In opening he alluded to the advantage possessed by the district in having a good secure rainfall, and described the land as "some good and some poor." Owing to these conditions he classified the district as eminently adapted for closer settlement practices in which the keeping of livestock might successfully be combined with crop-raising.

### INFERIOR CEREAL SEED.

The first query of the series submitted was—"Will inferior oats, the result of a bad season, but originating from good seed, produce a good grain when sown in an average season?"

The Director in reply said—"I take it that you have in view the exceptional conditions through which we have been passing. It is to be feared that not only inferior oats, but inferior grain of all kinds is being sown this season. In fact, owing to the position in which I happen to have been placed as Chairman of the Grain and Fodder Board, I have had an opportunity of realising more clearly than most how difficult it has been to secure seed of any kind, let alone good, clean, well-developed grain. Ever since November last we have, in the face of great difficulties, been endeavoring to secure seed wheat for those unable to obtain it for themselves. May I digress before answering the question? Well, at the expense of a great deal of trouble we secured three-quarter million bushels of grain, the great bulk of which has been distributed. We are now receiving a number of complaints from consignees. One must state that in such cases individual hardships were unavoid-

able. So far as the Agricultural Department is concerned, what with the purchase and sale of seed wheat, and the purchase and sale of chaff and other foodstuffs, a huge business was suddenly thrust upon them. This extraordinary development would have taxed the strength and business organisation of any ordinary firm to whom operations of that kind were familiar. Perhaps the Department have made occasional errors, but we are very far from being responsible for all complaints that are being made. The trouble is that we had in a very large measure to rely upon the good faith of those from whom we purchased grain and fodder. And in some cases I regret to say this confidence has been abused, and we get the blame. Much grain has been paid for as seed wheat by the Department which could never be sent out for that purpose."

#### EFFECT OF SOWING SHRIVELLED SEED.

"Now to revert to the question whether the lack of development in the seed will affect the quality of the next season's grain. In considering the matter we should recollect that any organised being—and seed is as much an organised being as a human—comes under two influences, namely, inheritance, which is fundamental and fixed, and environment, which is accidental and variable. You have your grain of oats, therefore, the result partly of inherited tendencies and partly of surrounding conditions. The first question then is—What are the inherited tendencies present in every oat grain, whether it is shrivelled or well developed? The answer is that they include all cultural characteristics of the variety, bred into it through a long succession of generations. You will get the same character of straw, the same color of grain, and the same size of grain, &c. It is as well to bear in mind that in so far as these characteristics are concerned the influence of a single season is practically nil. This means that, given favorable conditions in the present season, all the inherited characteristics should reappear in the new plants, whatever the character of the grain may be. This would seem to imply that shrivelled, ill-developed grain is quite as good for seed as large, plump grain. However, neither general experience nor direct experimental work in the subject confirms this view. Dr. Cobb, in New South Wales, conducted very careful experiments for over three years, and his final conclusions were very definitely in favor of the plump, well-grown grain. The fact is that we have yet to consider the influence of environment or surrounding conditions on the final development of the young plant.

"Now I think that we can summarise the influence of environment under the following headings:—(1) The start in life of the plant; (2) the ability of the plant to feed itself adequately; and (3) weather conditions throughout the period of growth. Now, we can rule out the last two points, because they would operate equally whether the grain was well or badly developed. There remains then for consideration the first point—the start in life of the

young plant. This may conveniently be divided into two sections under the subheads (1) germination, and (2) early development. Germination itself may be said to depend on the (1) vitality and healthiness of the germ attached to the grain, and (2) in suitable conditions of soil, of moisture, and of temperature. As the latter operates equally in all cases, the only point we need consider is the vitality and healthiness of the germ. Here, I am afraid, everything is in favor of the plump, well-developed grain. If you take 100 sound, plump grains, and sow them under favorable conditions, they should all germinate. The same is not the case with shrivelled, ill-developed grains, as a proportion, more or less great according to the circumstances, will fail. Hence the necessity with poor grain for sowing a greater number of grains to the acre—not necessarily a greater weight, as they are lighter.

“Lastly we have the early development of the young plant, and here again the ill-developed grain is at a disadvantage. The weight of the germ which ultimately develops into the oat plant is very inconsiderable—probably not 1 per cent. of the grain. One quarter of its weight is represented by husk, and the balance is food upon which the young germinating seedling draws in its early stages. This food is very largely in the form of starch. The germination process gradually liquifies it, and in this state it passes into the tissues that are being formed in the young plant. It is here that the ill-developed grain is at the greatest disadvantage. In this grain the amount of starch stored up for the young plant is never equal to that in plump grain, and the young plant suffers in the same way as a calf that is stunted of milk. It may recover in time, particularly in good, rich soil and in a favorable season. Generally speaking, however, the start will influence final growth and yield ; but it can have no influence on the plumpness or general development of the grain.

“To summarise these points—Plants produced from defective grain will germinate less freely and start off less well than those from good, plump grain. Yields of hay and grain will probably be lighter, but given good conditions, there is nothing to interfere with the quality. The latter is exclusively a factor of surrounding conditions.”

#### REASONS FOR SOWING OATS ON “TAKEALL” LAND.

“Why should oats be sown on land that was affected with takeall in the previous year?” was the second inquiry.

“This question,” said Prof. Perkins, “admits at first sight of a very short answer, viz.—If takeall is an infectious disease affecting wheat, and is present in the soil in which wheat has been grown, it is evidently wise to avoid sowing wheat in it for awhile ; and as oats appear more or less immune to the disease, they may follow as a rotation without danger and with advantage. Unfortunately, a very loose use has been made of the term ‘takeall,’ and it is

certain that quite a number of failures due to other causes have been ascribed to it. If, on the other hand, we confine the term 'takeall' to the ravages of the parasite known as the wheat stem killer, there is no doubt that the answer already given is sufficient. Wheat may, however, die out in patches or as whiteheads from quite a variety of causes. Eel worms, for example, may in damp localities gradually eat away the roots. Defective tillage, by leaving the land more or less hollow underneath sometimes leads to root failure on the part of the plant. Hot winds will also lead to the drying up of individual plants quite as readily as takeall. But, altogether independently of this fungus, it may be stated that the policy of growing wheat year after year on the same ground is not a good one. This is certainly the case in a district such as Inman Valley, which has a good rainfall. Other crops should be grown, such as forage crops or other cereals. The combined returns will be found more profitable, and little or nothing will then be heard of 'takeall.'

#### THE BEST OATS FOR HAY.

"What is the best variety of oats for hay?" was the next question.

"You cannot beat wellgrown Cape oats, which produces a beautifully fine hay," was the reply. "The only drawback to this variety is its liability to lodge, but this disadvantage can be overcome to a certain extent by lightly feeding off the crop in winter, and by not sowing too early. My next preference is Calcutta oats, which stands up well. Algerians are very freely used for hay. The objection raised against them is that they have to be cut very much on the ripe side to be at all palatable to stock."

#### COMPARATIVE QUALITIES OF OATS VARIOUSLY HARVESTED.

"Is the grain of an oat crop that is threshed or headed equal to stripped grain?" was the next query.

"The reply to this question," remarked Professor Perkins, "is that, providing the crop shall not have been cut too early, the grain will certainly be of equal, if not higher, quality. If the oat crop is cut too early, and particularly so if cut in hot dry harvest weather, the grain may shrivel appreciably. When the crop is cut the grain should be quite firm but not so hard as not to allow its being cut through with the fingernails. In these circumstances the grain will complete its ripening in the shade of the stook. It is essential, however, that the stooks be built up practically behind the binder. Long exposure to a hot sun, and contact of the heads with the hot soil, may even then lead to shrivelling. Under these circumstances the grain is said to be superior to grain cut dead ripe. Generally speaking, it has been shown that grain from a crop cut in a rather immature stage and allowed to ripen in the stook, has finer envelopes, and hence in gristing a higher proportion of flour and a lower proportion of bran.

## CULTIVATION OF ENGLISH BARLEY.

"Will English barley thrive in this district?" the Director was asked.

"I have every reason to think so," he said. "Malting barley does not need a soil of exceptional quality. Indeed, from the maltsters' point of view, grain grown in rich soil is generally glassy in fracture and inferior in quality. Moreover, rich soil leads to rank straw growth, with liability to lodge, and the blighting off of grain in summer. Light lands, with soils of moderate consistency, should be selected for barley-growing. The chief advantage of the Inman Valley district would be the more or less equable climate. This is essential to good quality. The usual obstacle to English barley production in South Australia is that grain ripens off too suddenly in the early summer, with the result that a thick, tough husk is formed, to which maltsters always take exception. The equable climatic conditions on Kangaroo Island explain the success met with there in the cultivation of English barley, and similar achievement should be possible in Hindmarsh Valley."

## SOILS WHICH BENEFIT FROM LIMING.

"Is lime beneficial to our heavy flats, and, if so, what quantities should be applied?" was the next question.

The reply was—"A question such as this does not admit of a direct reply without further knowledge of the conditions. In a general way lime is essential to plant growth in all soils. The plants need it for the building up of their tissues, and if it is deficient or absent, only certain special kinds will thrive and remain healthy. Where there is a deficiency the land is known as 'sour.' Lime, however, has other functions to fill beside supplying plant food. Its presence is necessary to maintain the soil in good mechanical condition in order that the roots may be able to circulate freely through it, and so that it does not become water-logged. This is particularly the case with heavy clay soils. Experience will readily teach you whether your soil needs liming. If water lies on the surface for a long time after rain; if the clay puddles so that you cannot work it for several days after rain; if it bakes down hard very quickly so that the favorable ploughing interval between too wet and too dry is very short—then, certainly, your heavy lands will benefit considerably from liming. In soils of this kind a dressing of about one ton to the acre is needed. The lime should be spread out over the surface early in the winter after the ploughing, harrowed in, and left for the rains to wash it down. This treatment, if the quantity applied is sufficient, will completely modify the nature of heavy clay. Water will not lie about, ploughing will be easier, the land will be less sticky and will not bake down to the same degree. Additionally, the feed will be earlier and more nutritious. Lime is also needed in soils for another reason. Changes in the surface soil, favorable to plant growth, are frequently due to the action of specific bacteria. These agencies need a neutral medium, and since they produce acids in their attack

on organic matter, &c., it is essential that a base be present to absorb it. Hence lime is necessary to the healthiness of the soil. In the absence of lime the soil becomes sour and conditions injurious to average plant life develop."

#### THE PRESENCE OF MAGNESIA.

The question, "Is magnesia injurious to fruit trees or lucerne?" was then replied to. The speaker explained that magnesia was usually present in the soil in several forms, which were not all equally injurious. Thus the carbonate of magnesia was almost innocuous; sulphate was injurious; and chloride most injurious. The addition of lime had the effect of converting the injurious forms into the comparatively harmless carbonates. The trouble was that magnesian salts were rarely alone, being usually associated with sodium chloride (common salt), and occasionally with sodium carbonate. The last-named, however, was not likely to be found in such a damp district as Inman Valley.

#### APPLICATION OF SALT TO PASTURE LAND.

"Is it advisable to apply salt to grass land in this locality, and, if so, what quantity is recommended?" was another inquiry.

The Director stated that it was a questionable practice to apply salt to grass land. The stock certainly needed salt, but it was preferable to provide them with salt licks. If the pastures were not nourishing, dressings of lime and superphosphates were likely to be far more effective than applications of salt.

#### MANURIAL REQUIREMENTS OF ORANGE TREES.

"What is the best kind of manure for orange trees, and at what time should it be applied?" was the next question.

The Director said that under ordinary circumstances the inquiry would be put to the Government Horticultural Instructor (Mr. G. Quinn), but in his absence, and with apologies to him, he would make the following remarks upon the subject:—"In the first place I am not aware that the question of manuring orange trees has at any time received careful and systematic treatment. If we take the practice of the older orange-growing countries in Europe, parts of Asia, and Africa, we shall find that the orchardists still pin their faith to heavy applications of stable manure. With them this type of manure appears to be the only one in use. In America, on the other hand, where probably the cost of handling a bulky fertiliser like stable manure would be considerable, a preference appears to be given to the more concentrated artificial manures. It is even said by the growers that experience there shows that stable manure, although favoring growth in the trees, has frequently an injurious influence on the character and type of the fruit grown. It is said, according to the Americans, to make the fruit coarse, thick in the rind, and to promote the production of an abundance of 'rag.'

Before making any specific suggestions as to manures which might be used with advantage in Inman Valley, it would be well to know what experience appears to have shown to be the special influence of the several ingredients present in most manures. It is found, for example, that the influence of phosphoric acid is felt chiefly in the fruiting of the trees. This phosphoric acid is present chiefly in the pips, and is therefore necessary to the normal development of the fruit. Additionally it is said to hasten their maturity. Potash is abundantly present in the fruit of orange trees, and its particular action would appear to be related to the formation of starches and sugars, and it is held in consequence that plenty of available potash is necessary to abundant fruiting. Potash influences the fruit to the extent of conferring upon it smoothness and thinness of rind, together with firmness and good keeping qualities. In addition to this it appears to influence the ripening of the wood. This is a point of considerable importance in a district subject to early autumn frosts. Nitrogen exercises its influences chiefly on the growth of the trees, and when present in ample sufficiency induces that dark-green foliage so characteristic of strong-growing plants, and also rather encourages the growth of vigorous, sappy suckers. An excess of nitrogen usually means the production of luxuriant growth, which yields comparatively little fruit. It also leads to the rather late ripening of fruit, which is generally coarse and thick in the rind. When nitrogen is deficient in any way the leaves of the trees become yellow and assume, generally, a stunted appearance.

"Finally, lime is also essential in a general way to the growth of any healthy tree. We shall realise, therefore, that in applying manures, much will depend upon whether the trees are young or whether they have attained the full fruiting stage. A young tree from which strong growth is chiefly required will need nitrogen to a greater degree than a full-grown one. Assuming the soil to be of moderate fertility, and that one wishes to force along young trees, the following dressing may be suggested for each tree:— $\frac{3}{4}$ lb. superphosphate,  $\frac{1}{2}$ lb. nitrate of soda,  $\frac{1}{2}$ lb. sulphate of potash.

"There is no doubt whatever that quite as satisfactory a result, if not a better one, can be secured from a dressing of farmyard manure dug well into the soil. For larger trees the quantity of manure to be applied will depend very largely upon the results one wishes to secure, but in any case it is worth recollecting that no tree can continue indefinitely to produce heavy crops of oranges unless liberally supplied with fertilisers. The following dressing for land of moderate fertility is suggested for each tree in full bearing:—6lbs. superphosphate, 4lbs. nitrate of soda, 6lbs. sulphate of potash.

"This may appear to be a costly dressing, but for trees which are each returning eight to 10 cases at average prices, the expenditure entailed is relatively inconsiderable. It should be added that it is by no means essential to use all the manures indicated in the formulæ given. In many soils no doubt the use of potassic manures may be unnecessary, and the same may be

said perhaps of nitrogenous agencies. It is a matter, therefore, for the grower to test for himself, and, profiting from the knowledge gained by this practical experience, to use only those manures that have been proved to give the most satisfactory returns.

"It is as well to apply dressings of the artificial fertilisers mentioned twice during the growing season, one-half of the quantities stated just before the trees begin to make new growth in early spring, and the other half about six weeks later. The manure should be distributed in a trench opened out round the trees at a distance from the trunk equal to the spread of the branches."

#### BURNT TIMBER AS POTASH PROVIDER.

"What are the valuable properties in wood ashes, and will it pay to gather them when burning up timber?" was the final subject.

The Director explained that the value of wood ashes varied according to the type of the timber burnt. "The chief useful ingredients in wood ashes," he said, "are salts of potash and lime. The potash is chiefly in the form of carbonates, and to a less degree in the form of sulphates, silicates, and, occasionally, chlorides. All these potash salts are soluble in water, and are therefore readily available to plants. There are also appreciable quantities of phosphoric acid. It should be noted, of course, that loose heaps of ashes exposed to rain lose much of their value, and that the figures I will give, indicating the percentages of salts present, refer to fresh ashes that have not been leached. From the small number of analyses we possess it would appear that the ashes of Australian timbers are less rich in potash than those growing in Europe. The following are a few examples of the composition of the local timbers:—

|                     | Phosphoric |         |       |
|---------------------|------------|---------|-------|
|                     | Potash.    | Acid.   | Lime. |
|                     | %          | %       | %     |
| 1 Mallee wood ..... | 2.42 ..    | 0.48 .. | 40.90 |
| 2 Stringybark ..... | 1.25 ..    | 0.82 .. | 8.54  |
| 3 Red gum .....     | 5.20 ..    | 3.20 .. | 35.98 |
| 4 Peppermint .....  | 4.06 ..    | 1.33 .. | 28.28 |

"Now, if we try to put a money value on the wood ashes of red gum, which are the richest of the four examples given, we shall base our estimate on 36/38 per cent. super. at £4 per ton on the one hand, and sulphate of potash at £14 per ton on the other. On this basis the value per ton of red gum wood ashes would be about £2 5s. 6d., with about 1,430lbs. of lime (calcium carbonate) thrown in.

"The average dressing of sulphate of potash for soils and crops needing this manure would be about 56lbs. to the acre. On the figures given this dressing will correspond to 10cwts. of mallee ashes, 19cwts. stringybark ashes, 5cwts. red gum ashes, and 6cwts. peppermint ashes.

"As to whether it will pay settlers to collect these ashes depends altogether on the labor involved in the operation. And with the data I have given I think that each individual should be able to work out this matter for himself. Owing to the abnormal conditions in which we find ourselves, it should be stated that instead of £14 per ton, as much as £30 per ton is now charged for sulphate of potash. And these prices are likely to continue throughout the duration of the war. In the circumstances, therefore, where potassic manures are required it seems certain that the collection of ashes will prove remunerative."

### IMPORTS AND EXPORTS OF PLANTS, FRUITS, &c.

During the month of May, 1915, 39,823bush. of fresh fruits, 6,732bush. of bananas, 19,317 bags of potatoes, 1,010 bags of onions, 6,432 packages of vegetables, and 60 packages of plants, trees, and bulbs were examined and admitted at Adelaide and Port Adelaide under the Vine, Fruit, and Vegetable Protection Acts of 1885 and 1910; 154bush. of bananas (over-ripe), and 9 packages oranges were destroyed. Under the Federal Commerce Act, 230 packages of dried fruits, 20 packages preserved fruit, and 8 packages plants were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 230 packages of dried fruit and 8 packages plants; for London, 2 packages preserved fruit; for India, 18 packages preserved fruit. Under the Federal Quarantine Act, 4,056 packages of seeds, bulbs, plants, &c., were examined and admitted from oversea markets; 1 package seeds rejected account of presence of proclaimed weed seeds.

During the month of June, 1915, 38,037bush. fresh fruits, 9,890bush. bananas, 19,460 bags potatoes, 755 bags of onions, 13,405 packages of vegetables, and 35 packages plants, trees, and bulbs, were examined and admitted at Adelaide and Port Adelaide under the Vine, Fruit, and Vegetable Protection Acts; 106 packages bananas (over-ripe) were destroyed. Under the Federal Commerce Act 47 cases of fresh fruits, 626 packages of dried fruits, 6 packages plants were exported to oversea markets during the same period. These were distributed as follows:—For New Zealand, 20 cases fresh fruit, 321 packages dried fruit, and 6 packages plants; for London, 5 cases dried fruit and 27 packages fresh fruit; for South Africa, 300 packages dried fruit. Under the Federal Quarantine Act, 885 packages plants, seeds, bulbs, &c., were examined and admitted from oversea markets. Thirty-one packages of seeds were rejected on account poor germination and presence of proclaimed weeds.

## TESTING DAIRY COWS.

*(Continued from page 897, May issue.)*

Dairymen will learn with satisfaction that herd-testing is now being carried on by the Department of Agriculture at the Stud Jersey Farm of Mr. H. C. Toppin, of "Kiama Farm," Plympton, and that of Mr. Peter Wood at Burnside.

In future dairymen having in view the improvement of milk and butter yields (through the medium of worthy sires), can select male calves, after first making a careful inspection of the official records which breeders will submit when selling. The keeping of such records will supply a long-felt want amongst progressive dairymen, in providing data to assist them in the selection of sires descending from pure ancestry which have proved themselves heavy milk and butter producers.

Buyers can carefully scrutinise the pedigree, both for purity and production, on the side of both the dam and sire. Hitherto no official or other sufficiently reliable records have been available. Is it any wonder, therefore, that many dairymen have been working as it were blindfolded in the breeding of dairy stock, having to rely merely upon pedigree and external indications as guides in selection.

I do not wish to convey the idea that dairy form is not of value as an indicator to production, but I do say that it is no proof of ability to economically produce milk and butter. At times I have asked those milking cows and about to commence testing, to guess at the amount of milk and butter some of their cows will yield during the milking period. After submitting the herd to the test, their figures have in almost every instance been very wide of mark, varying from 50galls. to 240galls. of milk for the lactation period, and as incorrect in their figures in regard to the amount of butter produced.

### GUESSWORK.

Guesswork has always proved unreliable, and will for all time be responsible for increased cost of production. During my long experience as manager of butter and cheese factories, I must admit that no farmer ever stated that he would accept guess weights. Farmers have always been anxious to secure credit for full weight in milk or cream delivered to a factory, and they will not allow any guessing at the amount of money they are to receive. Guesswork is practised only when dealing with the amount of milk he is getting from each cow consuming the food grown upon the farm.

Most dairy folk are of the opinion that they can get the best out of their herd for the food consumed, &c., without adopting any method of testing, but many of our most intelligent and progressive dairymen have made mistakes, and admit their inability to weed out the non-profitable cows without testing.

In New Zealand three testing associations tested 205 heifers not exceeding three (3) years old. Of these 68 were considered not worthy, and culled out after the first season. The 137 heifers left were again tested as 3-year-olds, and averaged 204lbs. butter-fat. A similar number of heifers belonging to members of other associations were not tested and culled until coming on as 3-year-olds, when the average result per heifer was but 186lbs., as against 204lbs., an increase of 18lbs. of butter-fat, or 21lbs. of butter in favor of selecting on records.

The answer given by farmers, when asked why they do not keep records, is practically the same in 95 cases out of every hundred, *i.e.*, "It is too much work." It is difficult to know how they arrive at this conclusion, never having tried it. It is indeed extraordinary when one gets the same reply from many men wide awake enough in other matters. Many animals subjected to the test prove little better than scrub cows, the percentage of these, of course, varying according to the care and judgment exercised by the breeder. There is only one reliable way known of computing the real earning value of a cow, that being by subjecting her to testing with the Babcock tester and scales.

Improved performance at the bucket is what should be demanded, and is most wanted to-day in the dairy business. This can most readily and economically be arrived at through breeding from approved sires combined with proper methods of testing and feeding at the farm.

Herd-testing has other objects than the correct estimation of each individual animal's milk and butter production. It is a medium whereby the dairyman adjusts the time of drying off and the freshening time of each cow. This item of regulating the period intervening between drying off and calving may not appear of much interest to our dairymen. I might here refer to one instance which came under my notice about a year or so ago, which forcibly impressed me as to the necessity for the utmost attention being given to this matter. A herd of 10 cows in milk were not stinted until from four to eight months after calving, thus averaging six months for each cow, with a full lactation period of 300 days. That meant that each cow remained out of work for a term of five and a half months in the year, *i.e.*, four months longer than is necessary. In a herd of 10 cows this means that practically three and one-third cows are remaining idle. On this basis, with a herd of 40 cows it would certainly spell bankruptcy, as no less than 13 cows would remain

Selected Stud Hefers (Owned and bred by Mr.) H. C. Toppin, Plympton.)

idle as profit yielders in excess of what is necessary in a well-regulated mating and freshening period. The above is based on the fact that these cows were only giving at time of visit 9galls. daily, and the period of gestation is 285 days.

#### SELECTION OF THE SIRE.

In the past too much importance has been given to pedigree, insufficient regard being given to the production records of the ancestry of the bull. It must not be understood that I discount the value of purity of blood, but there is a desire to place them of equal value. Purity of blood is indeed most important, but of little value as a guide to improvement of dairy stock unless it be accompanied by performances, which, if indicating heavy milk and butter production of ancestry, makes the animal highly valuable, and suitable for the purpose for which he is kept.

Some official records kept by this Department are now available, these being of cows owned by Mr. H. C. Toppin, Kiama Farm, Plympton.

| Barbara XVIII. ..         | "      | 5 3                          | 273                              | 5.07             | 5,135                           | 260.48                            | 299.48                               | 18                                      |
| Barbara III. ....         | "      | 16 9                         | 247                              | 4.76             | 4,171                           | 198.75                            | 228.51                               | 16                                      |

The average milk production of the 10 stud Jersey cows under review is 529½galls. of milk, average percentage of butter fat 4.8 per cent., average pounds of butter-fat per cow 256.34, average pounds commercial butter 294.72.

Included amongst this herd are "Rosette" and "Dainty" on their first calves, and Barbara III., an exceedingly old cow, whose full period was not completed; Mr. Toppin being desirous of securing a strong calf from her, deemed it advisable to dry her off, although, at the time of withdrawal from the test she was yielding 16lbs. of milk per day. Truly, her performance is wonderful for a cow of 16 years 9 months at date of entry, and when consideration is given to the fact that during her life she has produced no less than 18 calves, it certainly shows that this grand old cow must have wonderful vitality. Upon analysis her record should class her as a cow of good merit.

especially when it is generally contended that on average a cow's period of usefulness as a dairy beast has reached the limit when 12 years of age.

**Rosette.**

**Dainty.**

The result of the two heifers on their first calves, viz., "Rosette" and "Dainty" certainly cause one to reflect upon their merit. Although "Rosette" was 8 months older than "Dainty" at the time of entry, yet the former yielded no less than 224galls. more milk and 98·15lbs. more of butter-

fat, equal to 112·89lbs. of commercial butter. With butter at 1s. 6d. per pound, "Rosette" returned £22, as against £13 12s. 6d. by "Dainty" over the period of lactation.

**Barbara XVII.**—Owned by Mr. Toppin, Kiama Farm, Plympton. —Milk Yield, 6,423lbs. ; test, 4·76 per cent. ; butter, 351·85lbs.

**Barbara XVIII.**—Milk yield, 5,135lbs. ; butter, 239·45lbs. ; amount of Milk on last day of Test, 15lbs.

The above two cows are of nice type, and considering the droughty conditions obtaining during the past six months, the production of milk and butter of all the cows under review may be considered very satisfactory. The coming year, with better food supplies available, cows such as "Rosette," "Duchess IV.," "Barbara" XVII. and XVIII., will put up records very considerably in advance of those just completed.

Up to the present no other herds have completed the lactation period of 273 days, a comparison of the results must therefore be deferred until others have completed this period of official supervision.

## DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. Sandford & Co., Limited, report on July 1st—

**BUTTER.**—The bounteous downpours of May were followed by further splendid general rains last month, and consequently the outlook generally is brighter than it has been for many years past. Supplies of butter continue to increase, though with the mortality that has been recorded among the stock the improvement in quantity is not so rapid as would otherwise have been the case. Production is still short of local requirements, and importations continue to arrive. Values during the month maintained firm, in tops advancing a further 1d., "Alfa" reaching 2s. 1d.; Primus, 2s. 0½d.; choice separators and dairies, 1s. 9½d. to 1s. 10½d.; store and collectors', 1s. 6d. to 1s. 8d. per lb.

**EGGS.**—Values have kept up wonderfully well for the month, being quite 6d. higher than for the corresponding time of last year; hen, 1s. 6d. per dozen; duck, 1s. 7d.

**CHEESE** throughout the Commonwealth is very scarce, and as no imported has been on this market lately, it has been difficult to supply the trade with local lines that have been coming forward; rates 1s. to 1s. 0½d. per lb.

**BACON.**—Importations from New South Wales and Queensland continue to arrive, owing to local cure not being equal to requirements; sides selling at 11½d. to 1s. per lb.; hams, 1s. to 1s. 1d.

**HONEY.**—All prime samples of clear extracted are readily placed at 4½d. per lb., but second grades move slowly. Beeswax very saleable at 1s. 4d. to 1s. 5d. per lb.

**ALMONDS.**—Only odd lots coming to hand, it being between seasons; Brandis selling at 8d.; mixed softshells, 6½d. to 7d.; hardshells, 3½d.; kernels, 1s. 5½d. per lb.

**LIVE POULTRY.**—Competition throughout the month has been very brisk, and rates have advanced considerably, no doubt the high price of fresh meat causing a better inquiry for poultry, so that nice figures are likely to rule for some time to come. Good table roosters fetched 4s. to 4s. 6d. each; nice-conditioned cockerels, 3s. 3d. to 3s. 9d.; plump hens, 2s. 3d. to 3s. 2d.; ducks, 2s. 6d. to 3s. 9d.; geese, 4s. 6d. to 5s.; pigeons, 6d. to 7d.; turkeys, from 9d. to 11d. per lb. live weight for fair to prime table birds.

**POTATOES AND ONIONS.**—Supplies of potatoes in the South-East are practically exhausted, and for some months to come requirements for this State will have to be imported. During the past few weeks prices have doubled, in sympathy with the equally sharp advance that has occurred in Tasmania and Victoria. **Onions.**—Prime samples have become more scarce, and consequently rates have again slightly improved. **Quotations.**—Potatoes—Best Victorians, £12 per ton on trucks, Mile End or Port Adelaide. Onions—£8 10s. to £9 10s. per ton on trucks, Mile End or Port Adelaide.

## THE WILLIAM R. RANDELL LOCK.

November 3rd, 1829, is remembered as the date of the discovery by Capt. Charles Sturt of the River Murray. Since that time much has been done in the direction of utilising its resources, but June 5th, 1915, marks the genesis of a systematic national policy of developmental activity. The historic importance of the earlier event must be overshadowed by the economic value of the later—the new era of the Murray River.

This slow-flowing river with its tributaries is capable of being navigated over a length of 3,212 miles, apart from which its value from a

Trading Boats, River Murray.

standpoint of irrigation is practically inestimable. The vast tract of country which forms its watershed comprises an area of 265,121,920 acres.

### IRRIGATION.

Along the valley of the Murray in South Australia there is at present an area of over 25,000 acres irrigated or partially irrigated. There is also, in the opinion of the Director of Irrigation, an extent of considerably over half a million acres which is capable of being successfully irrigated.

Never in the history of the State has the value of water for irrigation been more strikingly manifest than during the past three seasons, and Australia has learned in the hard school of experience that to allow up to 1,305,000 million cubic feet of water in one year to flow lazily into the sea is false economy. The first premium of her "insurance against drought" policy has now been paid.

#### THE LOCKS.

The system of locks and weirs, of which the William R. Randell Lock is the first to be commenced, comprises a total of nine in all, six of which are to be in this State, and three between the eastern boundary of South Australia and Wentworth. It is anticipated that this

Reclaimed Area, River Murray.

will provide a navigable river with a minimum depth of 6ft. 6in. to Wentworth, a distance of 518 miles from the river mouth. No. 9 weir, which is to be constructed near the entrance to Fisherman's Creek, in addition to being used for navigation purposes, will be of service in diverting water into the Lake Victoria storage.

#### THE FIRST STONE.

To mark the occasion of placing the first stone in position, a Parliamentary party visited the site of the lock. The party included in its personnel His Excellency the Governor (Sir Henry Galway), who was accompanied by Mr. W. J. Gunson, the Prime Minister (Hon. A. Fisher), the Federal Attorney-General (Hon. W. M. Hughes), the Premier of New South Wales (Hon. W. A. Holman), the Premier of

South Australia (Hon. C. Vaughan), the Commissioner of Public Works (Hon. H. Jackson), the Commissioner of Crown Lands (Hon. C. Goode), the Minister of Industry (Hon. R. P. Blundell), the Tasmanian Minister of Lands and Works (Hon. J. Belton), the President of the Legislative Council (Sir Lancelot Stirling), the Speaker of the House of Assembly (Hon. L. O'Loughlin), and legislators of the different States, as follow:—New South Wales—Hon. R. D. Meagher (Speaker of the Legislative Assembly), and Mr. J. D. Fitzgerald, M.L.A.; Victoria—Mr. J. F. Hannan, M.H.R., Hon. R. B. Rees,

Raisin-Drying, River Murray.

M.L.C., and Mr. J. W. Billson, M.L.A.; South Australia—the Leader of the Opposition (Sir Richard Butler, M.P.), the Hons. D. J. Gordon, J. G. Bice, F. S. Wallis, J. P. Wilson, J. Cowan, E. Lucas, J. Jelley, M.L.C.'s, and Messrs. Smeaton, Denny, Anstey, MacGillivray, Chesson, Reidy, Ponder, Gunn, Hague, O'Connor, Tossell, Hill, Price, Coombe, Southwood, Parish, and Dunn, M.P.'s, and P. T. Heggaton (Chairman of the Railways Standing Committee); Western Australia—Mr. P. J. Burchell, M.H.R., and Mr. P. O'Loughlen, M.L.A.; Tasmania—Srs. Ready and Guy, and Mr. L. F. Giblin, M.L.A.; the Engineer-in-Chief (Mr. Graham Stewart), and the Director of Irrigation (Mr. S. McIntosh).

The first stone was placed in position by His Excellency the Governor, who was presented with a silver-mounted mallet by the Commissioner of Public Works (Hon. H. Jackson). The speeches delivered, and other particulars relating to the ceremony, are being published in souvenir form by the Intelligence Department.

Orchard, Kingston, River Murray.

Camel Team, Oodnadatta.

## SOUTH AUSTRALIAN PRODUCE IN ENGLAND.

### MANCHESTER GROCERS' EXHIBITION.

At the eleventh exhibition of the Manchester Grocers' and Allied Trades, held on April 12th to 22nd, 1915, South Australia was represented by a fine display of produce. The excellent means of bringing South Australia and its products directly under the notice of the consuming public at Home, afforded by displays at important trade functions, has been availed of with advantage on many occasions by the Trades Commissioner. Commenting on the exhibition under notice, Mr. C. F. G. McCann says:—"The opening ceremony was performed by the Agent-General for South Australia (F. W. Young, Esq.), in the presence of a large assembly. The Lord Mayor of Manchester (Alderman D. McCabe) presided, and was accompanied by the Lady Mayoress. Occupying seats on the platform as well were the Mayor of Salford (Alderman Worsley), the President of the Northern Council of Grocers' Association (Mr. J. Rushton), the President of the Manchester and Salford Grocers' Association (Councillor Whitwham), the Chairman of the Manchester Ship Canal (Mr. J. H. Bythell), Councillors Kendall, Glyne, Nixon, Greenwood, Barber, Milner, and Fox. The platform was artistically decorated for the occasion, a noticeable feature being the prominent display of the flags of the Commonwealth and South Australia.

"Great interest was manifested in the series of competitions open to grocers' assistants in connection with the following lines:—Tea valuing, tea matching, coffee roasting, butter and margarine testing, distinction in the country of origin (by tasting) of 13 samples of butter, parcel wrapping, lard weighing, bacon slicing, and window dressing. The majority of products for this competition were supplied from the South Australian stand.

"The South Australian Exhibit occupied a floor space of 50ft. x 16ft. An entirely new type of stand was adopted, which proved very attractive. The exhibits were arranged to combine as much as possible the elements of attraction without interfering in any way with the general business aspect of the products displayed. The effect achieved was much appreciated and commented upon, both by

the press and the public generally, and so much impressed the promoter of a similar show, which is being held in Norwich next week, that he made an offer to pay the cost of transit of the stand and

Manchester Grocers' and Allied Trades' Exhibition, 1915, South Australian Exhibit.

exhibits from Manchester to Norwich, and from Norwich to London, on the understanding that a similar display would be erected at the Norwich Exhibition. Needless to say, the offer was accepted.

“The products shown comprised preserved meat, wine, fruit (dried and fresh), olive oil, tomato sauce, honey and eucalyptus oil, the two latter products being on sale during the period of the Exhibition from the stand. Literature of all descriptions, illustrative of South Australia, its products and resources, was distributed indiscriminately, and the opportunity of obtaining first-hand information relating to our State generally was readily availed of by a much larger proportion of the attendance than is usual.

“I took the opportunity of interviewing nearly all the leading grocers and provision merchants with a view of future business, and am convinced that, provided supplies were available, there would be no difficulty in disposing of large quantities of honey, dried fruits, and preserved meats in and around Manchester. I introduced tomato sauce, and placed trial orders. I also disposed of 140 cases of honey in bulk, and was reluctantly compelled to cease taking orders owing to my supplies being exhausted. At the present moment, particularly in Manchester, there is a keen demand for all colonial States’ products in preference to those produced elsewhere, buyers appearing anxious to display a practical demonstration of their appreciation, by placing their business with us, of Australia’s efforts to assist the Mother Country, and it is to be regretted that the conditions of drought have prevented our State from being able to participate in a larger share of this business.

#### DRIED FRUIT.

“I gave particular attention to the dried fruit question whilst in Manchester, because I realise that with the development of the Murray River Irrigation Scheme the production of these products will be increased enormously, and I feel sure that unless a vigorous campaign of demonstration and advertisement is carried on at this end the best results in marketing dried fruits in England will not be achieved. The want of knowledge of the methods to be employed in the preparation of dried fruits for table purposes is very apparent here. We have endeavored to counteract this by issuing in pamphlet form at all shows the necessary cooking directions. Practical demonstrations, however, by testing counters at shows or in large shops are infinitely more convincing, and have now become the recognised method of featuring new lines of tinned and glass goods adopted by leading packers and large retail houses. So far, these methods have not been applied to the dried fruit business. I arranged a small demonstration through a firm of caterers in Manchester with a tray of pears and peaches, which were sampled by

prospective buyers, and the results were satisfactory enough to warrant a further trial of this method of advertising our dried products on a larger scale. Unfortunately, Australia generally in the past has achieved a doubtful reputation of being a 'country of samples,' due solely to the fact that, although the different States have made expensive and attractive displays at Grocers' Exhibitions, their representatives have not been in a position either to do business themselves or to indicate to prospective buyers where the goods exhibited can be obtained in England. I am approaching the houses in London handling South Australian fruits, and if successful in interesting them, I propose to begin the demonstrations at next season's exhibitions, commencing with the London Grocers' Show, to be held in September, and following up with Newcastle, Bradford, and Sheffield in the following months.

"Interviews were granted at Manchester, and information supplied to various persons relating to the following subjects regarding South Australia:—The River Murray irrigation scheme, poultry breeding, egg-laying competitions, oil prospects, bee-keeping, casing manufactures, artesian water supply, methods of handling wheat at ports, and marine fibre.

"Despite the war conditions prevailing, and the restrictions as regards street lighting at night, the attendance extending over the whole period of the show was estimated at 50,000 people."

Shipping Frozen Carcasses.

## PRUNING COMPETITION AT CLARE.

---

For the fourth successive year the Clare Branch of the Agricultural Bureau, on Monday, June 9th, carried its pruning competitions to a successful issue. "Bumburnie," the well-known garden of Mr. W. Pattulo, was again the scene of operations, and despite the inclemency of the weather—driving rain and bitter cold—the programme was carried out with enthusiasm and credit to all concerned.

The joint hon. secretaries of proceedings (Messrs. P. H. Knappstein and M. L. Nolan), with their previous experience of three competitions, left nothing to be desired in the way of arrangement, and the undoubted success of the gathering must be credited largely to their energy and foresight.

The attendance was very satisfactory. In addition to the members of the Clare Branch, visitors from Blyth, Watervale, and Mintaro, there were also present the Horticultural Instructor (Mr. Geo. Quinn), the State Viticulturist (Mr. H. E. Laffer), Mr. C. E. Birks (Member Advisory Board), and Mr. H. J. Finnis (Acting Secretary Advisory Board).

The financial success of the undertaking was largely due to the support of a large number of the business people of Clare.

The stewards, whose work was made particularly arduous by the weather conditions, were Messrs. F. Knappstein, W. J. Maynard, C. Neate, E. L. Elliot, E. Victorsen, J. Berridge, B. Lloyd, E. Dack, C. Radford, P. R. Pascoe, C. E. Birks, A. Hill, J. Dux, and F. Hicks.

### RESULTS.

*Currant Class* (two vines), judge Mr. A. P. Birks—Mr. H. Bartlett, 1st prize ; Mr. O. Dunstan, 2nd prize ; Mr. M. Smith, 3rd prize.

*Apples* (three trees), judge, Mr. J. Kempster—Mr. J. Brysky, 1st prize ; Mr. R. Glaetzer, Mr. F. G. Hicks, 2nd and 3rd prizes divided.

*Apricots* (one tree), judge, Mr. G. Quinn—Mr. J. Butler, 1st prize ; Mr. O. Dunstan, 2nd prize ; Mr. F. G. Hicks, 3rd prize.

*Peaches* (one tree), judge, Mr. G. Quinn—Mr. F. G. Hicks, 1st prize ; Mr. H. Baker, 2nd prize ; Mr. L. Jarman, 3rd prize.

*Sultanas* (two vines), judge, Mr. C. T. Jarman—Mr. J. Butler, 1st prize ; Mr. M. Baker, 2nd prize ; Mr. M. Bond, 3rd prize.

*Wine Grapes* (two trellis and two bush), judge, Mr. H. E. Laffer—Mr. W. Smith, 1st prize ; Mr. C. Barber, 2nd prize ; Mr. H. Baker, 3rd prize.

*Juvenile* (one sultana and one currant vine), judge, Mr. G. Lewcock—Mr. G. Pattullo, 1st prize ; Mr. P. Hicks, 2nd prize ; Mr. R. Hague, 3rd prize.

The aggregate prizes were secured by Messrs. J. Butler 1st, and O. Dunstan 2nd. The former secured 495 points and the latter 491 points of a maximum of 600.

#### JUDGE'S COMMENTS.

The Horticultural Instructor, in commenting on the work, said that in the apricot section there appeared to be a distinct improvement in the pruning when compared with that of last year's competition. A few of the leading discrepancies appeared to be the faulty method of treating aged wood shoots originating in the centre of the trees, which he suggested would be better dealt with in the summer time, the pruners in some respects not grasping the necessity for counteracting the evil effect of the past dry season, which had in the case of some of the trees considerably stunted the growth.

In the peach section the trees had not made vigorous growth, and the pruners generally appeared to be much more puzzled than in the case of the apricot. There being a large supply of flower buds on the fruiting wood in many cases, the pruners were disposed to leave too much weak fruit wood. In addressing the pruners he said that he was highly pleased with the general character of the work and intelligent grasp of general principles displayed by the majority. Faults of rough work, and permitting old decayed stumps to remain appeared to be rather a matter of carelessness than lack of knowledge of the necessary treatment of these parts.

In the evening, at the Institute Hall, a representative audience listened to an address by the State Viticulturist (Mr. H. E. Laffer) and the Horticultural Instructor (Mr. Geo. Quinn). The former took as his subject "Pruning of Vines Suffering from Effects of Drought," and the latter "Some Common Diseases of Orchards and Vineyards." Both lectures were illustrated by lantern views.

The prizes and certificates won during the day were then presented by the Acting Secretary of the Advisory Board (Mr. H. J. Finnis).

## ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, June 9th. There were present Messrs. G. R. Laffer, M.P. (Chairman), F. Coleman (Vice-Chairman), C. J. Valentine, T. H. Williams (Chief Inspector of Stock), C. J. Tuckwell, J. Miller, C. E. Birks, W. J. Colebatch (Principal of Roseworthy College), A. M. Dawkins, Professor Perkins (Director of Agriculture), and Mr. G. G. Nicholls (Secretary).

### CONFERENCE OF RIVER MURRAY BRANCHES.

On the recommendation of the Renmark Branch it was decided that the annual conference of the River Murray Branches of the Agricultural Bureau should be held between November 20th and December 10th.

### LIABILITY OF NURSERYMEN.

The Waikerie Branch intimated that it was of the opinion that in the interests of orchard owners there should be enforced in South Australia an Act similar to the Nurserymen's Liability Act in Western Australia, for the reason that many orchard owners, through the carelessness of nurserymen, had been put to considerable expense and trouble, because trees supplied had not been true to name, and, further, weak trees and diseased deciduous trees had harbored diseases, which had been spread through the district. A member of the board suggested that perhaps itinerant nurserymen from another State had been responsible mainly for the position. "As a rule," remarked the Chairman, "South Australian nurserymen are good reliable men." Continuing, he said, "If you deal from a reputable firm you can generally be certain that you will get what you want. Still, there may be some merit in the Western Australian Act." At the instance of Mr. Dawkins, it was resolved to refer the matter to the Government Horticultural Expert (Mr. Quinn) for a report.

### VETERINARY INVESTIGATION WORK.

Mr. Dawkins suggested that more investigational work should be performed by the Government veterinary staff, which was a very fine one, and as a step in the right direction, he proposed that the Minister of Agriculture should be recommended to station a veterinary surgeon at Roseworthy College, "in the midst of stock and the

proper surroundings," and enable him to undertake such work. Mr. Coleman seconded the proposition. Mr. Colebatch pointed out that it would be quite impossible for a veterinary surgeon stationed at the College to conduct exact investigational work and at the same time teach students and perform other duties. For the time being, at any rate, he felt that they must be content to rely on the veterinary institutions in other parts of the Commonwealth for the results of intricate and exact investigational enterprise. He was strongly in favor of having resident at Roseworthy College a veterinary surgeon, who would be able to give lectures, make certain general investigations at the College, and keep an eye on the health of the stock in the district. Such an arrangement would have the advantage of facilitating the instruction of the students in connection with the care and treatment of livestock, and at the first favorable opportunity he would endeavor to secure such an appointment. The motion lapsed.

#### IRRIGATION COLLEGE.

The following resolution from the Bookpurnong East Branch of the Bureau was received:—"That in view of the big future ahead of the irrigationists on the River Murray the Advisory Board be asked to recommend the Government to establish a college for irrigationists on the Murray, and combine with it the raising of suitable dairy stock and kindred callings allied with intense culture." Mr. Colebatch submitted that there was no need to duplicate the staff at the Roseworthy College, where the science of irrigation was already being taught. All that was required to make the instruction complete was a better supply of water for the various irrigation plots. Professor Perkins endorsed Mr. Colebatch's views, and strongly emphasized the necessity for a great improvement in the water supply. It was intended now, he believed, to make provision at one of the irrigation settlements on the Murray for a combined dairying and fruitgrowing experiment farm. Mr. Dawkins considered it would be a farce to have a college for the teaching of irrigation alone, and that any course of instruction for intending irrigationists should cover the whole science of agriculture, as was now taught at Roseworthy College. It was decided to put the position before the Bookpurnong East Branch, and to endeavor to secure the augmentation of the water supply at Roseworthy College.

#### SUMMER FODDERS ON SANDHILLS.

The Bookpurnong East Branch also desired that experiments should be made at Veitch's Well Farm in the growing of summer fodders, especially on the sandhills, with a view of preventing drift.

Professor Perkins explained that so soon as the land on the farm had been properly cleared it was intended to proceed with experimental work along several lines, which would certainly include the raising of summer fodders. In fact, a start had already been made in that direction.

#### SEED WHEAT.

The Carrieton Branch of the Bureau forwarded for inspection by the Board a sample of "seed wheat" which, it was stated, had been received through the Grain and Fodder Board. The sample was shockingly smutty, and as one member sarcastically observed, "Not fit even for fowls." Mr. Nicholls, who is Secretary of the Grain and Fodder Board, pointed out that supplies of seed wheat had been sent to between 4,000 and 5,000 farmers in different parts of the State, and certainly not a dozen complaints of the kind before them had been proved to be well founded. He doubted, indeed, whether more than a dozen complaints altogether had been received. There had been two or three cases in which agents had sent out wheat which was altogether unsuitable for seed. On the motion of Mr. Tuckwell, the secretary was instructed to write to the Carrieton Branch and inquire whether the sample forwarded was truly representative of the bulk of the wheat supplied, or whether it was merely a sample of tailings?

#### FARM LABOR.

Mr. Miller said he had read with much pleasure the observations and recommendations made by the Director of Agriculture in his annual report regarding the training of lads with a view of providing suitable labor for farmers, and proposed:—"That the Board approves of the suggestions, and appoints a committee, comprising the Director, the Principal of Roseworthy College, the Chairman of the Board, the Vice-Chairman, and the mover, to consider the matter, with the object of rendering assistance to the Director in the furtherance of his proposals." Professor Perkins mentioned that there was unquestionably a need for good farm laborers, a need which, he thought, could be met to some extent by training lads of 18 or 19 on the Government farms. These young men, of course, would not be students, but merely apprentices. There were five or six Government farms—and possibly the number would be increased—on each of which several youths, who would do a part of the work, and obtain a good insight into farming methods and practices, could be accommodated. His idea was that for the first six months they would receive 5s. a week and their keep, the second 10s., the third 15s., and the next £1 a week. They would then be retained on

the farm if there was room for them, or be provided with certificates, should they prove to be satisfactory, which would ensure them getting work as first-class farm laborers. The motion was agreed to.

#### DISEASED STOCK.

Mr. Williams suggested that owners of livestock should be impressed with the necessity for communicating, in writing, with the local Inspector of Stock, and also with the Chief Inspector of Stock, in Adelaide, within 24 hours, respecting the appearance of any proclaimed disease among their animals. Through the failure to do that in the past much trouble and inconvenience, and no doubt some loss, had occurred.

#### LONG FLAT BRANCH.

A request from the Long Flat Branch to close same and transfer interested members to the newly-formed Branch at Murray Bridge was agreed to.

#### NEW MEMBERS.

The following gentlemen were approved as members of the Branches shown:—Naracoorte—W. W. Gould, jun.; Meadows—A. L. Pinches, W. Holder; Salisbury—G. M. Heddle, F. W. Sayers, H. A. Webb; Sherlock—S. Wheaton; Elbow Hill—H. J. Wheeler; Clare—C. Lord, W. Pointing; Waikerie—J. A. Bamnear, H. Renk, J. B. Murdock; Blyth—A. J. Weber; Morphett Vale—J. E. Sullivan; Kybybolite—L. S. Davie, J. E. L. Porter; Crystal Brook—J. R. Saltmarsh, F. W. Kloppe; Gladstone—Archibald Lewis; Geranium—J. Young, R. Young; Milang—J. McMillan, A. Moar; Carrow—F. Pugsley; Renmark—H. Berriman; Keith—A. J. and L. Densely; Strathalbyn—J. W. Elliott; Langhorne's Creek—H. Follett; Mount Barker—J. Lance Neagle, C. Liebelt, P. F. Liebelt, J. F. Liebelt; Willowie—D. E. Greig, F. T. Wood; Wepowie—R. Halliday; Pinnaroo—A. H. Symonds; Forreton—A. Hanna; Gumeracha—J. E. Hamlin; Elbow Hill—R. W. Bunn, W. Surfield, P. Surfield, O. G. Styles, A. Tilley, C. F. Jenkins; Waikerie—H. Barrett, J. Stokes, R. Notman; Mount Remarkable—E. Sheppard, P. Cape; Rockliegh—R. W. Rolland; Brinkley—A. Forrest.

#### LIFE MEMBER.

Upon the unanimous request of the members of the Mount Gambier Branch, Mr. A. J. Wedd was made a life member of the Bureau. Mr. Wedd had been a member for over 26 years, and had rendered sterling service to the Bureau and the agricultural interests of his district.

## POULTRY NOTES.

By D. F. LAURIE, Government Poultry Expert and Lecturer.

### COLLECTING AND MARKETING EGGS.

This subject is not new, but it is of sufficient importance to justify further consideration. On various occasions when lecturing I have described the formation of the egg, the process of fertilisation, and its subsequent extrusion in the form we well know. An understanding of these facts will serve to impress upon poultry owners the importance of many points.

#### THE EGG.

It is commonly believed that the number of potential eggs contained in a pullet is about six hundred. This number was computed by a French observer many years ago. Recent investigation shows that this number may be greatly exceeded. Eggs have their immediate origin in the follicles, or folds of skin, in the ovary. In the embryonic state the female of the fowl has two ovaries, one on each side of the backbone, but in adult life there is, as a rule, only one which functions—the other having degenerated, is not visible. Each egg—or ovum—is enclosed in a delicate membrane called the ovisac, and this is connected with the follicle by a stalk or pedicle. This pedicle contains blood and other vessels from which the ovule is nourished and stimulated. The egg substance itself is but food-stuff after due elaboration. It represents, in poultry, a food store from which the embryo develops into the future chick. If a pullet approaching laying condition be killed and dissected, the ovary will be a very prominent object. It will appear as a bunch (grape-like) of spheroids, in size from a pin's head to the mature yolk. If the examination be made soon after death, it will be noted that the ovary and its adherent ovules and their sacs are highly vascular (*i.e.*, well supplied with blood vessels). Examine a full-sized yolk in its enclosing sac, and you will notice that it is deep orange in color, and that there is a band of very light color round the middle of the egg sac; this is the stigma, and is the point at which the sac ruptures or splits when releasing the matured yolk. Further examination will reveal the blastoderm or germ vesicle on the yolk. This appears as a light colored circular spot, about one-eighth of an inch

in diameter. This same spot can be easily identified if an egg be broken into a large cup so that the yolk may float on the egg white (miscalled albumin). In the egg the yolk always so floats that the germ disc is on the upper side—the reason is that there is a difference in the specific gravity of the upper and lower portions of the yolk. Further examination of the pullet will reveal a flesh colored tube connected by membranes with the bowel. This tube is the oviduct or egg tube. The upper end is free; the lower end communicates with the cloaca, or pouch, into which the bowel also discharges. The upper end of the oviduct is called the ostium tubae—or infundibulas portion; it is funnel-shaped, membrane-like, but well supplied with muscles and nerves. When the yolk in the ovary is matured the egg sac ruptures at the stigma, and simultaneously the funnel-shaped end of the oviduct rises and grasps the yolk as it emerges from its sac. The sac is in evidence for some time, but is gradually absorbed and disappears from view. Occasionally when examining a hen an egg yolk will be found in this upper portion of the oviduct, and without any deposit of egg white. It is then similar in general appearance to the yolk as seen in an egg which has been broken into a cup or basin. There are, however, microscopic differences in the case of a fertilised egg.

#### FERTILISATION.

It is opportune to point out that at this point the egg may become fertilised, if the female has been running with a male bird. Fertilisation can only take place in the oviduct, but not in the ovary. When the sexual act takes place there is emitted by the male bird a whitish fluid, which may contain a few, or many thousand, spermatozoa—the male germs. Only one spermatozoon is necessary for the act of fertilisation. The spermatozoa are microscopic, and need special technique and a high-powered microscope to reveal them. These spermatozoa progress through the oviduct towards the free end. They progress by characteristic spiral, wave-like motions, in the fluid of the oviduct. On reference to the egg yolk it will be noted that the egg yolk substance is contained in a delicate structure known as the vitelline membrane. The spermatazoon consists of three main portions—the head, the neck, and the tail. It has the power to penetrate the delicate blastoderm, or germ skin, covering the germ vesicle, and contained in the light colored, circular spot previously referred to. In the eggs of certain insects there is a minute hole here, called the micropyle; but in the hen's egg there is none, but a condition arises due to nervous stimulus which encourages the effort of the spermatazoon to penetrate. That act accomplished, the condition immediately

changes, and no other spermatazoon can gain entrance. On consummation of the act of fertilisation the tail of the spermatazoon breaks off, but the head part can be detected for some time afterwards. Fertilisation is a fusing of the male and female germ cells; actual fusion from the point of heredity does not take place, however, because the male and female elements lie side by side in the germ vesicle. From a vital point of view, the important part of the egg is the germ vesicle, where fertilisation takes place. The yolk of the egg, and later on the egg white, &c., are only important to the embryo as special stores of food. There is a close relationship between the amount of yolk and egg white and the subsequent embryo of various species.

It has been stated by some writers that the egg can be fertilised in the ovary; but this is not so. The fact that one service of the male bird may fertilise many eggs is not due to this, but because the spermatazoa may exist in the oviduct for many days, perhaps weeks—dependent upon the fact of acidity or alkalinity of the fluids. Recent work has shown that, in some species, a cubic centimetre of seminal fluid may contain not a single spermatazoon or there may be many millions. Nature is often prodigal in these matters.

#### COMPLETION OF THE EGG.

Returning now to the egg yolk, which is still in the extreme upper portion of the oviduct. The following happenings result:—The whole length of the oviduct is muscular as well as vascular and nervous. A stimulus is imparted by the entry of the egg yolk, and various happenings take place in turn. The most important is what is known as *peristalsis*—the motion of the tube due to the special muscles acting under nervous stimulus. The peristaltic action forces the egg with a spiral movement along the oviduct. In the upper portion, and as far as the *isthmus* it receives various coats of egg white, of varying degrees of density. It then receives the two membranes, the inner and outer, and then the shell is deposited by special glands. When this process takes place the egg occupies a pouch-like enlargement of the oviduct termed the *uterus*; it also receives by osmosis a further addition of egg white. The egg shell consists of lime (carbonate and phosphate), and although deposited as a fluid crystallises into minute prisms, with minute spaces (so-called pores) intervening, which serve for the respiration of the embryo and for general gas exchange. In hens of breeds which lay eggs with tinted shells there is an addition of pigment, secreted by special glands. Shortly after the egg is laid. As a rule the process of enveloping the yolk has occupied about 16 hours or 17 hours. The egg yolk contains 16 per cent. of protein and

30 per cent. of fats, oils, &c., 1 per cent. of mineral salts, and 53 per cent. of water. The white contains 12 per cent. of protein, 2 per cent. fats, &c., 1.20 per cent. salts, and 84.80 per cent. water.

#### FERTILE AND INFERTILE.

This is the history of the fertile egg. You cannot decide without breaking an egg whether it is fertilised or not. All sorts of pretensions to do so have been claimed—the fact remains. On breaking an egg into a cup persons with reasonable eyesight can generally distinguish that in the fertile egg there is an inner ring, inside the germ disc. Microscopic examination—a somewhat delicate proceeding—however, shows that there is a vast difference between the germ disc of a fertilised egg and that of an infertile egg. When the act of fertilisation took place there was the junction of two cells—male and female. This double cell divided, and each part matured and divided again. By the time the egg was laid it was found that there had been a great aggregation of cells in the germ layer.

#### THE MARKET EGG.

For market purposes we do not require a fertilised egg. We have seen that the egg is formed in the hen's ovary without any help from the male bird. Fertilisation is, therefore, an accident—it is quite unnecessary to the maturation and formation of a perfect egg. We see that when an egg is fertilised there is a growth of cells—life—in the germ layer. Life persists until some action, such as prolonged cold, destroys it, or until increased temperature starts activity, and the subsequent apparent growth of the embryo (chick). Where there is life, then, there is danger to the egg as an article of diet. You cannot guarantee a fertile egg to keep for any period, however short. An infertile egg has long keeping powers, but may deteriorate if exposed to

#### UNDESIRABLE SURROUNDINGS.

There is a large fat content in the egg—the yolk contains 30 per cent. Fat retains odors. Eggs packed in contact with strong-smelling substances, and even stored in rooms tainted by strong-smelling substances, will absorb this odor and retain it. Of more importance, however, is the straw lining the nest, and the chaff used for packing. Some months ago a case was investigated by me. New laid, infertile eggs, which had been washed, were packed in perfectly sweet, dry wheat-head chaff. On arrival, a week later, at their destination it was found that many eggs appeared to be rotten and the chaff badly “mildewed.” It was thought that the eggs had become wet during transit; but it was not so. Investigation showed the cause of the

trouble. The eggs were washed and placed on a wire netting frame to dry. They were not dried with a cloth, as should have been the case; consequently, they were packed with a small drop of moisture on the shell. This caused dampness, fermentation in the straw, and bacterial action. The bacteria gained entry through the "pores" in the eggshell, and the contents were contaminated, and soon became black and "broken up." A laboratory test was made, with precisely similar results. Doubtless many farmers and others, not knowing the danger, may use damp packing material, or may pack damp eggs. When packed the eggs may have been all that could be desired, but when opened out would be a mass of corruption. The following are a few

#### POINTS TO BE OBSERVED.

Get rid of your surplus male birds. Establish breeding pens; but, except during the breeding season, keep the male birds penned securely, and away from even the breeding hens.

Hens and pullets for market egg production will lay more eggs, and the eggs will be of the best value for trade purposes if they are infertile.

Wash all soiled eggshells and carefully dry before packing. Use plenty of clean, dry straw for the nests, and see that the nests are dry. Collect the eggs daily, and send them to market twice a week at least.

Pack dry eggs in dry, clean, sweet-smelling chaff in sound cases; or, better still, use proper egg crates fitted with cardboard fillers.

If every person having to do with market eggs would pay due attention to all these points, the saving to this State would be the greater part of the £60,000 estimated as the annual loss through rotten and broken eggs.

There will be a good market for all the eggs South Australia can produce, but we can never hope to obtain satisfactory results unless we produce and market a first-class article. The oversea export trade will come again in the near future, but only absolutely sound infertile eggs will be of any value. Buyers in the other States could pay more money for our surplus eggs if the risk of losses were not so great. It is of no use breeding good poultry, housing and feeding them well, if our products are placed on the market in poor condition. The proper marketing of both eggs and table birds is a lesson which all our farmers and breeders should study at an early date.

Storekeepers and packers should pay special attention to the question of packing material and packages. Also, they should pass the eggs along to market with a minimum of delay.

## THE WHEAT MARKET.

## LONDON (Previous Day).

| Date.  |                                                               |
|--------|---------------------------------------------------------------|
| June 2 | Dull.                                                         |
| 3      | Dull, with easier tendency.                                   |
| 4      | Weak, with downward tendency.                                 |
| 5      | Unchanged.                                                    |
| 8      | Very weak; 9d. to 1s. lower.                                  |
| 9      | Very dull, and lower to sell 1s.; 2s. 6d. lower.              |
| 10     | Dull, and offered lower.                                      |
| 11     | Very weak, 9d. to 1s. lower.                                  |
| 12     | Dull, and offered lower.                                      |
| 15     | Quiet.                                                        |
| 16     | Very dull, 1s. 6d. to 2s. 6d. lower.                          |
| 17     | Very dull, and lower to sell; good demand.                    |
| 18     | Unchanged.                                                    |
| 19     | Easier.                                                       |
| 22     | Quiet.                                                        |
| 23     | Weak, with downward tendency.                                 |
| 24     | Firmer; Liverpool market dull.                                |
| 25     | Firm, rather dearer; Liverpool market steady; slightly firmer |
| 26     | Steady but quiet.                                             |
| 29     | Unchanged.                                                    |
| 30     | Firm, and held higher.                                        |

In South Australia wheat was quoted at 7s. 6d. per bushel for ordinary f.a.q. on trucks Ports Adelaide, Pirie, and Wallaroo, at the beginning of the month; on the 10th June prices ranged from 7s. 6d. to 7s. 9d. Parcels remain at 8s. 3d to 8s. 4d. per bushel on trucks, Port Adelaide.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall for the month of and to the end of June, 1915, also the average precipitation to the end of June, and the average annual rainfall.

| Station.                   | For June, 1915. | To end June, 1915. | Av'ge. to end June. | Av'ge. Annual Rainfall | Station.               | For June, 1915. | To end June, 1915. | Av'ge. to end June. | Av'ge. Annual Rainfall |

\* No report received during the month of June.

† Formal report only received.

‡ Held over until next month.

## ADVISORY BOARD OF AGRICULTURE.

### Dates of Meetings—

### July 14th and August 11th, 1915.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

Edited by H. J. FINNIS.

#### UPPER-NORTH DISTRICT.

(PETERSBURG AND NORTHWARD.)

MORCHARD (Average annual rainfall, 11in. to 12in.).

April 24th.—Present: nine members and two visitors.

BINDER AND HEADER.—Mr. S. H. Parsons advised farmers to cut from 20 acres to 30 acres of their wheat crops with the binder each season, and put it through the header. The crop to be treated should be cut from 6 days to 10 days before it would be ready to reap with the stripper. The straw, properly stacked and thatched, would stand for years without deterioration. If the grain was not a good sample it should be crushed and fed to stock. He suggested that every three or four farmers should co-operate in the purchase of a header. The secretary (Mr. H. G. Kupke) said that for 18 months he had been feeding headed straw, some of it 10 years old, to horses. The animals were doing the farm work, and remained in good condition. Messrs. R. Kitto and B. S. McCallum supported the recommendations of the speakers.

MORCHARD (Average annual rainfall, 11in. to 12in.).

May 29th.—Present: 15 members.

CO-OPERATION.—The Chairman (Mr. R. Jasper) read an extract from the *Journal* on this subject. Mr. W. Toop said that experience in other States had shown that co-operative concerns had proved beneficial to the producers, and were also financially successful. Mr. W. A. Toop said that if farmers co-operated better markets could be found for their produce, and they would be able to buy machinery, cornsacks, and other requisites at considerably reduced rates. The Secretary (Mr. H. G. Kupke) said by co-operation farmers would be able to market their wheat in big parcels, and would therefore secure higher monetary returns.

TARCOWIE (Average annual rainfall, about 15½in.).

April 28th.—Present: 11 members.

PIG-BREEDING ON THE FARM.—Mr. Shrowder read the following paper on this subject:—"The strong demand for pigs that now exists is the cause of more than usual attention being paid to this class of stock. To judge from present appearances it seems almost impossible to overbreed for some time to come. However, it is not here advised that the ordinary farmer should go in for such breeding at the expense of his other stock lines, but it is advised that he breed pigs steadily, and in moderate numbers. Pigs are animals that multiply very quickly, and this fact should go far towards preventing any large number of farmers undertaking the business on a big scale, for past experience has demonstrated that a slump in such stock is of benefit to no farmer. In connection with the sudden drop in the price that has in the past been such a feature of the pig market, however, it may be considered that the various restrictions, sanitary and otherwise, have very seriously reduced the number of those who may be termed the itinerant pig breeders, and as these were responsible to a great extent for the glutting of the market when prices began to lower, it is probable that for some time, may be

for all time, fluctuations will be less than of yore. Now, with the class of stock intended for meat, it is an important item to feed and manage them in the way best calculated to secure a quick growth and early maturity. Under usual conditions, no pig should be kept on the farm, except as a breeding animal, until it is a year old. To a very considerable extent, the growth must be encouraged from the start, a ration calculated to make a good frame and secure good development of bone and muscle, and, at the right stage, to fatten, being fed. An animal kept in good, thrifty condition during growth will usually need but a short period on a good fattening ration to finish for market. But it is not desirable to keep any class of growing animals fat, and here the judgment of the feeder must be exercised as to the condition of the animals, and the ration must be determined accordingly. With an animal intended for meat, it is a very exceptional case in which it can be considered to be growing too fast. One of the best seasons for hastening the progress of the pig is when grass and clover have made sufficient growth to furnish a full feed, but in order to make the most of this, the pig should be in a good, thrifty condition. It will pay better to feed a little extra to maintain a steady growth than to allow the pig to run down. In the past few years views as to fattening of live stock have been changing, and the opinion has gained ground that too much importance can be attached to the nitrogenous constituent of the ration; there is a danger perhaps that too much importance may now be attached to starchy foods. Certainly a perusal of the results of the many feeding experiments which have been conducted for years past suggests that the importance of nitrogenous foods as against starchy has been over estimated. Experiments have shown that potatoes are the only food that pay the cost of cooking for pigs. It is believed that raw potatoes have a certain poisonous influence, possibly on account of the alkaloid solanine present, which is more or less modified by cooking. Experiment has shown that 4lbs. of potatoes are equivalent to 1lb. of maize in pig feeding. Milk forms a valuable part of the animal's ration. All grain should be soaked, and is still better if crushed and soaked. The pig relishes a moist diet rather than a dry one, and will give better returns for the same food after soaking a few hours than if fed dry. The old practice of permitting the feed to ferment and become a source of annoyance on account of the offensive odor it gives off is no longer followed by the intelligent feeder. The average weights of pigs are:—Porkers, from 76lbs. to 80lbs.; baconers, 120lbs. to 130lbs.; choppers, from 300lbs. to 500lbs. Some breeds mature quickly, others slowly; some are reared for hams, others for bacon, and so on; practice always being ruled by the market. The breed mostly favored in Australia is the Berkshire, although several others are now becoming more evident. The Berkshire is, perhaps, the most popular, because of its general hardiness. It can withstand the heat better than most breeds, is thrifty, fattens readily, and the flesh is of good quality, with fair distribution of fat and lean. But young, juicy, sweet, mild-cured bacon and hams are foremost in public demand, and consequently curers prefer pigs weighing about 120lbs., rather than older pigs of greater weight, and are prepared to give a better price per pound for them. Heavy-weight back-fatters do not in many instances pay for the cost of keeping and fattening. The most profitable animals are those secured by mating large Yorkshire boars with Berkshire or other suitable sows. The Mid-Yorkshire pigs are not a success as regards the production of profitable progeny, and though the pure Berkshire is a fine animal for the production of hams, it does not yield the total weight of flesh that is obtainable from the large Yorkshire-Berkshire cross. White pigs are worth 5s. a head more than the black, and the use of the Yorkshire boar produces white pigs, and promotes big litters. Under natural conditions the pig is a grazer. Better pork is obtained from the animal which is run in a small paddock, and sty-fed at the last, than from that which is sty-fed throughout. Sties should be airy, but not draughty. They should be in such a position as to be open to the morning sun, and should be well drained. Bedding is necessary when the weather is cold, and especially for the sow at farrowing time. The breeding sow should not be kept too fat. Pigs of all ages should have access to plenty of water. Too much attention cannot be given to the selection of breeding stock, as a false move in its selection will affect a great number of progeny. Select from reputed and long-established stock. Pure-bred pigs should be chosen. See that the sexual organs of the boar are well developed. The breeding animal should be of a large litter. See that the sow's teats are well developed. There should be 12 or more. A boar should be first used when eight or nine months old, according to the

breed, and the sow should be put to the boar when nine months old. The period of a sow's gestation is 16 weeks. The sow, when near farrowing, should be kept away from other pigs, as she is liable to be injured. Plenty of short bedding should be allowed. If the straw is long, young pigs are apt to be smothered and injured. The sow generally farrows without any serious after effects. The feed for a short time before and after delivery should be soft and sloppy, such as crushed grain or pollard, and some green feed of any kind; but no hard or dry feed should be given. Two ounces of sulphur and a little nitre will help the sow if she is at all constipated, and a little exercise every day will also do much good. Generous feeding is required, or all will suffer. The time for weaning will vary a little, according to circumstances, but from eight to nine weeks will generally be found most satisfactory, and if the sow is available, it is better to let the pigs suckle until they are from 10 to 12 weeks old. Farmers often wean pigs when they are only six weeks old, but unless there is an abundant supply of milk, and particular attention is given to them, the pigs are likely to become stunted, sometimes so severely that they never recover. The best way to advance young pigs is through the feeding of the sow. She has a strong digestion, and can turn coarse grains and pasture into easily digested milk. Careful experiments show that a pound of weight taken from the sow will make more than one pound of gain in the pigs. The sow should be fed to produce a high yield of milk, and the young pigs should be kept with her until they are capable of eating a full feed of both grain and pasture. When the time comes to wean the pigs, reduce the sow's rations to water and a little grain. Take away the stronger pigs first, leaving the weaker to suckle for a few days longer. This method will give the weak pigs an extra chance, and will dry up the sow without injuring her. A sow comes in season about four or five days after the pigs are weaned, about 10 to 14 days after that, and then every three weeks regularly. Under ordinary conditions a sow will rear two litters a year. Young boars can be castrated when four weeks old. In castrating a ruptured pig great care must be taken, and in every case the incision must be sewn up. Feed the young pigs at short intervals; they fatten more quickly, and do not waste so much as is the case if fed less frequently and given bigger feeds. A fat pig will dress up to 90 per cent. of good meat, and will weigh 10 or 11 times the weight of his head. It makes all the difference in the profits whether the sow produces good, strong pigs, and then feeds them well, or produces a litter of weaklings and has nothing for them to eat, whether their system is nice and cool, or hot and feverish. In the one case she will be good natured and let the pigs suck, and will furnish plenty of milk; in the other, fretful and peevish, and very probably she will eat her pigs as soon as they are born. These conditions depend largely, if not entirely, upon the manner in which the sow is treated and fed during pregnancy. It is a very rare occurrence for a brood sow running on pasture to eat a pig. The best food for a brood sow is coarse wheat, middlings, or reground bran, or these may be mixed in equal proportions and made into a stiff mash with skim milk or table refuse. The sow should have access to a box filled with a mixture of six parts charcoal, two parts wood ashes, with 2lbs. of salt, and  $\frac{1}{2}$ lb. copperas added for each bushel. Water should be available at all times. Many experienced pig-keepers recommend the use of a moderate dose of flowers of sulphur and Epsom salts given once a fortnight during warm weather. It acts in a beneficial manner on the blood. Charcoal is unquestionably a very valuable hygienic agent for pigs. It is a corrective, and undoubtedly prevents some diseases arising from disordered digestive functions. A point should be made of seeing that charcoal or wood ashes, which act similarly, are kept within reach of the pigs, so that they can help themselves when they feel inclined. Those who feed pigs for their own use generally give them a feed or two of corn daily for 14 days before they are killed. It should be remembered that the better the feeding the finer will be the pork. For a nourishing diet the best materials are barley and pea meal; and if milk, either skimmed or churned, can be given at the same time, it will greatly assist the growth and improve the quality of the flesh. A good plan to follow before killing is to give the pigs nothing else but churned or skimmed milk to drink; and for a day before killing, the pigs should not get any food. Where people's circumstances will not permit any of the modes of feeding for killing which I have above pointed out, boiled potatoes, mixed with a handful or two of oatmeal may be resorted to as a substitute. It is undeniable, notwithstanding what has been said above, that the Irish peasantry produce excellent pork by feeding their pigs almost entirely on potatoes, but it is not so fat as the pork

produced from peas and barley. It is only by co-operative enterprises that real success can be achieved in pig-rearing, and if the farmers do not heartily support such businesses the prospects of the industry are likely to remain very poor throughout the State. It costs no more to breed good pig stock on our farms than it does inferior, but the profit to be obtained from the superior pig is a big consideration. It is a matter of profit or loss; satisfaction or disappointment. So, if we desire the former, let us make an effort in the direction of the general improvement of our pig stock on the farm." Mr. W. J. Nennis cited his experience with pigs, and said he favored the Essex-Berkshire cross for marketing purposes.

#### WARCOWIE (Average annual rainfall, 12.16in.).

June 1st.—Present: seven members.

CO-OPERATION.—In a paper on this subject, Mr. G. Growden said that if farmers were to place orders for their requirements through the medium of the Bureau a considerable saving of expenditure could be effected. In the case of fertilisers, if the members of the Bureau could make up one large order for their needs, there would be keen competition amongst manufacturers to secure such an order, and a price would be quoted which would be a considerable reduction on the prices they had to pay under existing circumstances. This system would also be applicable to the purchase of other of their requirements. In the marketing of their products also, co-operation would assist if their wheat yields were massed together and sold in one big parcel. A higher price would be secured than if sold in small lots. Co-operative ownership of farm machinery was another phase of the question. A large, portable chaffcutting plant could be purchased for the use of farmers in one particular district. In the slack period of the year, this could be moved from place to place, and sufficient chaff cut on each farm to meet the owner's requirements for a year. A threshing plant could be used in the same manner. Members discussed the matter, and the hope was expressed that, as a result of the next Congress, a workable co-operative scheme would be formulated.

#### WEPOWIE (Average annual rainfall, 13in. to 14in.).

May 25th.—Present: nine members and three visitors.

Mr. J. Chrystall read a paper dealing with "Care of Farm Harness." New harness, he said, should have a dressing of neatsfoot oil before use. This would keep out the sweat, and prevent the harness becoming hard. All harness should be oiled at least twice a year, and when repairs became necessary they should have immediate attention. Collars which caused sore shoulders should be restuffed, so that they would fit the horses' shoulders properly. Horses should not be fed with their collars on, as it was not only annoying to the horses, but caused damage to the collars. Harness, in his opinion, should never be hung in the stable, but should be put away in a room set aside for the purpose, and everything in the harness room should be methodically arranged to save time in harnessing up teams.

#### WEPOWIE (Average annual rainfall, 13in. to 14in.).

June 22nd.—Present: 13 members and one visitor.

This being the annual meeting, the Secretary read the report for the preceding 12 months. The average attendance of members at each meeting was nine.

FENCING.—Mr. H. Noske read a paper on this subject. He advised the use of gum posts from which all bark had been removed. They should be placed about 30ft. apart, with two iron standards between. Strainers should be 18in. to 2ft. in thickness, where they were placed at corners, and it was wise to use two in such cases. On even ground strainer posts should not be more than 150yds. apart, and where the ground was uneven they should be closer. Where the fence was intended to keep in big stock two barbed wires should be put at the top of the fence, one on top of the posts, and the other through the posts. Four plain wires should be placed at intervals under these. All wires should be kept tightly strained. Where netting wire was erected the wires should be attached to the sides of the posts, so that the netting could be better and more easily fastened. Four inches of the wire netting should be placed underground to prevent rabbits burrowing under the fence.

WILLOWIE (Average annual rainfall, 11.90in.).

May 25th.—Present: seven members and two visitors.

Mr. B. E. Schmidt contributed a paper on the subject of "Farm Implements." He classified the various implements required for farming, and dealt with the advantages and disadvantages of various types. He said that stump-jump ploughs were becoming increasingly popular, and they appeared to him to be the most practical and of the lightest draught. In stiff soils, however, set ploughs were preferable as they ensured a uniform depth of cut. He considered a plough made to cut a width of 7½ in. to be the most suitable implement, as this would allow for the increase in width which the plough would cut as it became the worse for wear. The most serviceable cultivator for use in all classes of soil was the stump-jump double V-shaped type. Disc cultivators were extremely useful for work in ground containing rubbish, but they were handicapped by serious disadvantages, such as side draught, and the flattening of the surfaces of the tines after use. Spring tine cultivators were very useful for pulverising and loosening the soil preparatory to drilling. The common set harrows were the most useful type of that implement, and, in his opinion, should be more frequently used, both on fallow and sown land. Discussion of the paper followed. Mr. Hawke had made use of an attachment for a spring tooth cultivator, for the purpose of destroying weeds on land of a light, loose nature, which was free of stones. The device consisted of a thin, flat steel sharpened like a blade. This was affixed to the back tines of the cultivator, the others having been removed, and was worked just under the surface of the soil. He found this both economical and effective in its work. Members generally agreed that lightness of draught was one of the main factors to be taken into consideration in the selection of an implement.

WIRABARA (Average annual rainfall, 18.91in.).

April 4th.—Present: 21 members and one visitor.

BEE-KEEPING.—Mr. P. J. Curnow contributed a paper on this subject. He traced the history of the industry from the earliest times, and dealt with the progress which had been made during latter years. He said that the very first question requiring attention was that of finding a suitable honey-producing country, and then a suitable location for an apiary. In this State timbered areas were scarce, and the novice in apiculture had little choice if forest trees were to produce his honey crop exclusively. Where many varieties of trees were found there should be a good honey district. If, on the other hand, cultivated crops such as lucerne and clovers were to be depended upon, the choice was widened. Bees should do particularly well where irrigation was followed as a means of crop production, as by this method the beekeeper was more independent of seasonal changes. Having selected a district, next came the question of site for an apiary. The writer favored a gully running east or north-easterly. In such a position the rows of hives faced north or north-westerly, and after many years' experience he was convinced that bees did best if they faced in this direction, as then they had the sun on their hive fronts all day long. The old theory that bees should face the east had nothing to support it. He had bees in three locations, one lot facing east, and two others facing north-west, and he found the two latter the more profitable. The South Australian type of Langstroth hive was the best for their district. The cover was high, and if fitted with ventilators, would withstand a very hot summer. He had tried flat covers, such as were used in Victoria, and the bees left the hive on a hot day. The ordinary hybrid bees gave good results, but to secure the best returns over a number of years it was wise to requeen every now and then with new blood from good stock. The improvement in modern bees was most marked. The pure Ligurian had evolved races of better honey gatherers, and it paid to buy the very best queens from men who specialised in their production. Having then stocked an apiary in a suitable district, many points had to be considered to make a success of the undertaking. Firstly, avoid over-stocking. If there were other bees in the district they should attempt to find out the carrying capacity of the timbered areas in average years, and then not increase the number of hives beyond a profitable limit. In the Wirrabara district, in the writer's opinion, from 60 to 80 hives made up a sufficiently large apiary for one site. If it was desired to increase the number of hives they should be placed in out-apiaries not less than two miles apart. In every case clean water should be available in the hot months, as a very considerable quantity

was required by bees in a heavy honey flow. In reference to the interior working of the hives, full sheets of foundation comb should be used in the frames. Not only did bees work up more rapidly, but the production of drone comb was prevented by its use. It was unwise to use less than full sheets in the top stories. During a dearth of bloom disturbance of the brood nest should be avoided. Bees resent too much disturbance, and there was always the risk of losing or injuring the queen in a swarm. All that was necessary, under such circumstances, was to ascertain that the bees had enough honey stored to keep them going, and a sufficient number of bees to keep the hive in fair working order. After such an absence of honey-producing flowers, and as soon as bees began to move under the impulse of a steady honey flow, the hives should be thoroughly overhauled. When honey was coming in the queen would start to lay. The brood combs should be spread, and empty, clean, and drawn out worker combs placed between them. If this practice were followed judiciously every week or 10 days swarms in otherwise good order would very rapidly increase in size. When swarms were always backward, rarely ever reaching the stage when an upper or honey-producing story could be placed on the hive, such swarms should be carefully watched, and if no improvement took place, the queen should be killed, and the hive either given a new laying one from a nucleus, or a comb of eggs not more than three days old from the best hive in the apiary. It was a good plan to allow swarms to remain queenless 20 hours before giving such a comb, as every bee in the hive would then realise its queenless state, and take more readily to the eggs given. To secure suitable eggs a comb should be removed from the best hive, in the centre of the brood nest; an empty, clean worker comb should be put in its place, and generally in one or two days the queen would deposit her eggs, when the comb could then be removed to the queenless hive. If it happened that a number of queens were needed after the cells were sealed over, all but one firm comb of eggs should be taken away. A queen cell should be placed in a comb in each queenless hive, when in a few days it would hatch, and much time would be saved. When small swarms were found in an apiary they could be built up by giving one or more combs of hatching brood each time the hives were examined, that was to say, once in seven to 10 days during a good honey flow. The beekeeper should make sure that each hive had enough combs to keep the bees busy. If they were working very industriously and the upper story was not filled with combs they would soon build on top of bottom frames and in curves, thus wasting time on work that had to be destroyed. Where many bees were kept a four-frame reversible honey extractor was a profitable investment, as very rapid work could be effected by its use. Many beekeepers did not season their honey sufficiently before selling. The writer recommended the use of a number of storage tanks in which honey should remain for at least a week to settle and clarify. He often retained the honey in tanks for a whole month if tank space was not required. In this way a very great improvement took place in the flavor, as the water collected by the bees evaporated, leaving the honey pure and very much thicker. Unripened honey, when sold, had done a great deal to bring eucalyptus honey into discredit, owing to its rank flavor. Some hives, generally single ones, would send out six to 10 small useless swarms if allowed to do so. Although it meant a lot of work and attention it was wise to overlook every eight days or so, destroying all queen cells not wanted. If no swarms were required, this plan was the only practical one to follow. The most modern type of Ligurian queen swarmed but little, although in some seasons even these would average one or two increases. The common hybrids would, in a good season, swarm indiscriminately. One of the worst pests in a hive was a drone-laying or unfertilised queen. She produced only drone eggs, and would lay three and four eggs in one cell. Where such drone larvae was present, the bees raised the tops of the common worker cells higher than the ordinary, and the experienced beekeeper could tell at a glance the condition of such a swarm. The queen should be killed. After 24 hours the swarm should be given a new queen or a new comb of worker eggs, not more than three days old. Every comb containing eggs by the late queen should be removed at the same time. It was absolutely necessary that eggs from which queens were to be raised should not be more than three days old. While queens could be raised from eggs five days old, they only lived half the time the others did. The writer advocated stimulative feeding if a prospective honey season warranted it. The present season had confirmed this opinion. For weeks past, the box trees (*Eucalyptus hemiphloia*) had been flowering magnificently. Owing to the absence of a honey flow earlier in the season, and also to

the absence of a pollen supply local swarms were too weak to take advantage of such a splendid honey flow, and local beemen regarded the season as a failure. Had local bees been fed for a few weeks prior to the opening of the flowers, no doubt tons of honey would ere this have been exhibited. The feeding was a simple matter. The very best white crystal sugar must be used. For a stimulative food crystal sugar should be dissolved in an equal weight of water. For heavy winter feeding two and a half times the quantity of sugar to a given quantity of water should be used. The syrup should be placed in common saucers on top of frames, each saucer having a deal float in it. This prevented the bees drowning. Feeding should be done late every evening. A month's feeding of even a saucerful would work wonders. Queens would commence to lay, and in this way would have swarms in good order by the time the natural honey was available. The feeding of a substance to produce pollen (used in the hive to make beebread to feed young bees), had attracted a good deal of attention from beemen in the eastern States this season. Such meals as linseed, peasm meal, brose meal and others had been tried, but only with partial success."

#### WIRABARA (Average annual rainfall, 18.91in.).

May 29th.—Present: 17 members.

**THE MODERN SEED DRILL.**—Mr. J. Jericho contributed a paper on this subject. The modern seed drill, he said, had been designed to meet the shortcomings of the broadcaster. He compared the several makes of seed and fertiliser drills, and pointed out the advantages and disadvantages of each. For good, level ground a 21-hoe drill was the most economical, but if the land were uneven, a smaller size was to be recommended. Rubber tubes were superior to steel tubes, as the latter were apt to stretch and allow the wind to distribute the manure, and also allow moisture to enter and clog the tubes. Disc drills were preferable to hoe drills on rough country or stubble ground, as the former would not be choked by the collection of rubbish. The harnessing of horses to a drill could be so arranged that the shaft horse with a saddle could bear the weight of the drill, instead of the weight bearing on the horses' necks. Breast chains could also be used in place of pole straps, and wear of the collars could be so avoided.

**AMYTON, May 25th.**—**MARRAM GRASS.**—The use of this grass to prevent sand drift was discussed. Members were of opinion that, as the drifting in their district was occasioned by drought conditions, and would cease with the growth of natural grasses and herbage, artificial grasses need not be encouraged.

**MOUNT REMARKABLE, May 6th.**—It was reported that the demonstration plots prepared by Mr. N. S. Giles gave no results. In the small plots arranged at the school by the Hon. Secretary (Mr. H. H. Davie) the plants did best where the seed was sown 4in. deep. Members indorsed the proposal re show judging made by Mr. Pearce, of the Yadnarie Branch, and suggested that cards showing the points scored should be exhibited upon the pen, yard, stand, &c. On the motion of Mr. G. Casley, seconded by Mr. N. S. Giles, it was decided to recommend to the authorities that grass parrots be taken off the list of protected birds.

**ORROROO, May 29th.**—**CO-OPERATION.**—This subject was discussed by members, who did not favor the establishment of any further co-operative institutions.

#### MIDDLE-NORTH DISTRICT. (PETERSBURG TO FARRELL'S FLAT.)

**BOOLEROO CENTRE** (Average annual rainfall, 15.83in.).

May 24th.—Present: eight members.

**QUANTITIES OF WHEAT TO SOW.**—The Secretary (Mr. G. Ashley) read some extracts from a statement made by the Superintendent of Agriculture in Victoria (Mr. A. E. V. Richardson, M.A., B.Sc.), to the effect that for sowing in April less seed wheat was required than was needed for later sowings. Members generally held the opinion that as the rain did not always fall early in the district it was safer to sow the maximum quantity in case some of the seed failed to germinate.

**HORSE BREEDING.**—Mr. R. W. Stanton read an article on this subject. Members were unanimous in declaring that no class of horse, suited to local requirements, could be found to excel that already in the district.

**CANOWIE BELT** (Average annual rainfall, 20.04in.).

June 23rd.—Present: 13 members.

**FARM MANAGEMENT.**—Mr. M. E. Redden contributed a paper on this subject. He said that when harvesting machinery was finished with for the season it should be thoroughly cleaned, overhauled, and placed in a shed for protection from the weather. Worn parts should be replaced, and a coat of paint would assist in the preservation of the implements. Wheat crops intended for seed should be allowed to stand until fully ripe before harvesting, and care should be taken to keep each variety separate. A good pickling vessel could be made of 14in. Oregon plank-ing. The dimensions should be 42in. by 24in. by 18in. The pickling solution should be made by dissolving 1lb. of bluestone in 10galls. of water. A well pulverised seed bed was essential to successful seeding operations; if the land was lumpy the drill should be preceded by a roller, and after the first good rain the harrows should be run over the ground. In fallowing operations the land should be harrowed and cross-harrowed. Sheep should be kept to assist in the destruction of weeds. Harness should not be left in the stables, but should be put away in a room adjoining the stables. In spring all harness should be washed in warm water, and when dry should receive a good dressing of neatsfoot oil or tallow. A blacksmith's shop was indispensable on a farm. The past season had taught them that they must conserve their fodder resources. Straw should be cut and stacked to meet emergencies. Messrs. Dowden and Carter emphasized the necessity for careful consideration in the purchase of implements. Mr. Kirk said that if horse collars were put away secure from the effects of damp weather, horses would not have sore shoulders so frequently.

**CO-OPERATION.**—This subject was introduced, and the discussion which followed was adjourned until the next meeting.

**CRYSTAL BROOK** (Average annual rainfall, 15.62in.).

May 26th.—Present: 19 members.

**LESSONS IN FARMING.**—A paper on this subject was read by Mr. Teakle. He said the common idea that a farmer had only to plough and sow to reap a good harvest was a fallacy. Experience taught many lessons. When building it was a bad policy to put the barn and the stable together. They should be separate, as the risk from fire was lessened. A thrifty and industrious wife, who took an interest in poultry, was a big factor in commanding success. Quality stock was more profitable than inferior stuff, and cost no more to feed. Before the drought some farmers had fed their stock too liberally. One man had confessed that he could have done with 10 tons of hay less than he had used in the good seasons; and when drought came he was obliged to send his horses away for agistment. He pointed out the necessity for the conservation of water, cocky chaff, and straw. Where possible, the farmer should put down a bore to obviate the necessity for water-carting. In the future irrigation would have greater vogue, and farmers would find the production of more green fodders essential. During the good seasons the men on the land should make the most of their opportunities. In the discussion that followed Mr. Pavy advocated the planting of trees that could be lopped in times of necessity to provide feed for stock. Messrs. Venning, Heaslip, and Dennis strongly advocated the policy of fodder conservation.

**LAURA.**

April 30th.

**THE DAIRYING INDUSTRY.**—In a paper on this subject, Mr. L. Giles said that an important factor in successful dairy farming was the selection of a farm capable of providing an abundance of green feed, and more particularly during the summer months. For this reason the South held an advantage over the Northern districts. The next important point was a herd of cows that had been graded and tested. Most farmers, for some reason best known to themselves, looked upon the testing and weighing of milk from each cow as waste of time. He had tried two ways of testing cows. Firstly with a Babcock tester, and weighing the milk, testing the milk once every four weeks, and keeping account of each test; and secondly,

by weighing each cow's milk separately, separating and churning the cream into butter. If two gallons of milk would make a pound of butter, the cow was giving a 5 per cent. test. Secondly, if two gallons of milk made  $\frac{1}{2}$  lb. of butter the cow was testing very nearly 4 per cent. Again, if two gallons of milk would make 1 $\frac{1}{2}$  lbs. of butter the cow was establishing a 6 per cent. test, which was seldom reached. This, to his mind, was the simplest way for a man with two or three cows to ascertain what they were capable of producing. He urged every member to try his cows in this way. Perhaps it would mean that some of the favorite cows would have to give place to others less valued by them. He thought a very good average for cows would be between 500galls. and 600galls. of milk per year, producing about 250lbs. of butter. To bring about these results they would need to study more closely the breed of cattle most suitable for their district. For instance, some cattle seemed to feel the cold of winter months more than others. He favored the Ayrshire breed. They were hardy, and seemed to do better, proving themselves more suitable for most countries, more especially hilly districts, than other breeds he had had experience with. The most important factor in securing a good milking strain of cows was the keeping of a pure-bred sire from a good milking strain. With careful grading and testing it was possible to build up a herd of cows that would not only pay for feeding, but would leave a good profit for the farmer. The only satisfactory way to handle milking cows was to have a good shed, giving each cow a separate stall, so that each received its share of food. Quietness in handling, and cleanliness were essential.

#### LAURA.

May 28th.

VARIETIES OF WHEAT.—Mr. E. T. Hughes submitted a paper on this subject. There were almost an unlimited number of wheats which did well in good seasons, he said, but to secure the best average results it became necessary to study the chief characteristics of the varieties and select those that proved the best in adverse circumstances. Three or four varieties were generally sufficient for one farm, and for their district he had no hesitation in placing Early Gluyas first, Marshall's No. 3 second, Silver King third, and Comeback or Federation fourth, according to conditions. To secure the best results from the varieties named it was necessary to study their habits of growth and ripening, the quality of grain and straw, whether they were suitable for hay or grain, or for both. Silver King was a rather late variety, though not so late as Dart's Imperial. He would sow it first because it stood well. It produced a big growth of soft straw. It was a large-grained wheat with a light, soft chaff, and was easily handled by the harvester, giving a good clean sample. It should be cut for hay as soon as the grain reached its full size. It made a good marketable chaff with a fair amount of grain and a good green color. Gluyas Early should be sown in mid-season, preferably the second or third week in May. It was a fine-strawed wheat with a short head, yielding heavy crops of either hay or grain, always showing to great advantage in bad years. It was a particularly hardy wheat, and stood dry weather better than anything else he had seen. This wheat should never be sown early, as it would then reach its heaviest stage just about the end of September or beginning of October, the time when the heavy winds were most likely to occur. It was a particularly good wheat to reap, and cleaned well, and even if tangled would reap fairly well with the aid of a false comb. It was a close, hard-chaffed wheat, which enabled it to resist frost and keep a good color in wet weather when ripe. The bushel weight of this variety at times was as great as 66lbs. The chaff was rather hard when harvested, but if tossed into a heap and a good stack of straw placed on top of it, it would soften wonderfully. This wheat should not be cut for hay until the grain toughened, the straw would then have a good color and weigh heavily. When chaffed it should be cut as long as possible in order to make chewing by stock necessary. This wheat should never be sown late, as it would run up to head with the first dry weather, and most likely give a smaller yield than a later wheat. It was a poor stooler, so should be sown fairly thickly; one and a quarter bushels to the acre gave good results. If sown on light, sandy soil it would produce a thin crop, and a thin crop of Gluyas was difficult to bind should it be more profitable to cut for hay, which, of course, was determined by market prices. Gluyas was a splendid wheat to sow on a dirty piece of land, as it would be ready for the binder just as

the oats were full and milky, thus enabling the farmers to clear their land, and at the same time cut both wheat and oats at the period most suitable. Marshall's No. 3 being a good stooler, fairly hardy, and rust-resisting, should be sown last. This wheat would yield more heavily if sown earlier, but when used in conjunction with the two former varieties a higher average yield would be obtained than if either of the others were sown last. It gave a good cut of first quality hay, a good sample of grain, and also good quality cocky chaff. It is slightly tough wheat to thresh, but cleaned well, and would be a real good wheat to harvest with the binder and header. Being a little on the tough side it would give good straw (much to be preferred to that stripped and then bound) and would not knock out or break up in carting, as would Silver King or Gluyas. Marshall's would not head with the first dry weather, but after a rain it would head well and produce a good marketable sample. Federation should be sown early and in wet or hilly places. It stood up well and did not shake out. It was difficult to clean with the harvester, being somewhat light, and it was more economical to use the stripper for this variety. Comelback was one of the best milling wheats grown. It yielded well when reaped for grain, and gave a good cut of hay, but should only be grown where rough winds were not troublesome, as it was liable to shake out badly. It was a fairly early wheat, a fair stooler, and easy to handle with the harvester, yielding a thin skinned grain. In conclusion he recommended the three first-named varieties. They would do well anywhere if sown as suggested. Federation should never be sown late, as it was apt to rust, should it make a quick and sappy growth, which it was likely to do if weather conditions were favorable after late sowing. Mr. Blesing said that in the Bangor district Gluyas was found to be the best all round wheat. Early Gluyas took second place to Late Gluyas, which was a heavy cropper. It had a stiff straw, and was a superior grain. Marshall's, in his opinion, should not be sown late, as it was affected by hot weather. Silver King had not proved a success in hilly districts. Federation should be sown early, as it was a soft wheat. Some interesting experiments were conducted in the Telowie district a few years ago with drought resisting wheats. The rainfall during the wheatgrowing period was 3½ in. In these experiments Bunyip gave the best results. Mr. W. Stevens said that in the Wirrabara district Gluyas was found to be a good wheat when sown in sheltered places, but it went down in rough weather. Federation was also a heavy yielder in that district. Steinwedel had produced a heavy crop, but it should not be harvested with a stripper but with a binder and threshed. Mr. R. Cleggett considered the best all round wheat, one suitable for hay and grain, was Marshall's No. 3, but it should be sown early. Mr. Giles said that in the Booborowie district Federation had proved to be the best all round wheat. Mr. E. Peck had found Silver Dart a good all-round wheat in this district; it could be sown early or late. He had sown some, with satisfactory results, as late as August. King's Red was also a good wheat.

#### MUNDOORA (Average annual rainfall, 14.11in.).

May 24th.—Present: seven members.

LUCERNE GROWING ON A SMALL SCALE.—Mr. M. Dee described his experiences. He recommended spreading a good dressing of stable manure over the land before ploughing it to a depth of 6in. or 7in. in May or June. He cultivated it till the end of July or early in August, and sowed from 8lbs. to 10lbs. of seed on rich soil, and from 10lbs. to 12lbs. on poorer classes of land. He preferred cutting small plots with the scythe or sickle, and used the sprinkler for distributing the necessary water. Members generally considered that a small plot of lucerne was a boon to the farm poultry during the summer.

#### PORT BROUGHTON (Average annual rainfall, 14.44in.).

May 28th.—Present: six members.

CO-OPERATION AND MEDICINE CHESTS.—It was decided to allow the delegates of the Branch attending the September Congress to use their discretion in voting on proposals for co-operation. Members believed entirely in co-operation, but they did not think the propositions put before them would be practicable in South Australia. It was decided to inform the Pine Forest Branch that the purchase of veterinary instruments and a medicine chest would be a waste of money, as no one would be able to use the appliances, and medicines required could be procured from local shops.

**DEMONSTRATION PLOTS.**—The Secretary (Mr. J. H. Fletcher) reported that except for notes on germination the hand plots were a failure. Six plots were sown on June 16th, on hungry, black oak land. The soil was just damp at 3½in., and was as dry as ashes below that depth.

*Results Showing Germination.*

| Plot.    | Condition of Seed. | How Treated or Sown.           | Grains Sown. | Grains Germinated. |
|----------|--------------------|--------------------------------|--------------|--------------------|
| 1 .....  | Bunty              | Pekled with bluestone (1 in 3) | 36           | 29                 |
| 2 .....  | Bunty              | Dry .....                      | 44           | 17                 |
| 3 .....  | Clean              | Bluestone (1 in 8) .....       | 41           | 38                 |
| 4 .....  | Clean              | Dry .....                      | 42           | 40                 |
| 5 .....  | Clean              | Depth 3½in. ....               | 17           | 13                 |
| 6* ..... | Clean              | Depth ½in. ....                | 17           | 17                 |

None of the plants were sickly in the early stages.

**PORT GERMEIN** (Average annual rainfall, 12.84in.).

May 15th.—Present: six members.

Mr. Carmichael delivered an address on the subject, "Can we Profit by the Past?" He said the last season had been a very distressing one, and the little wheat that was grown had had no more than 3½in. of rainfall. There was insufficient rain to pack the soil, and under such circumstances, in his opinion, the drill should be followed with a sub-packer. He also emphasized the value of thorough working of the soil. A great loss of stock had been experienced, and a considerable proportion of this loss had been caused by blood worms and sand. For blood worms, he recommended Fowler's solution of arsenic, dose two tablespoonfuls in bran morning and evening. More provision should be made to store cocky chaff. Messrs. Deer and Stone commented on Mr. Carmichael's remarks. The latter gentleman had found milk and honey very useful for sand. Dose four cups honey, one quart milk.

**SPALDING** (Average annual rainfall, 20.25in.).

May 21st.—Present: seven members and one visitor.

**TREE PLANTING.**—Mr. E. E. Gill read a paper on this subject. He said that in a district like Spalding, which was devoid of all trees, plantations were of great value in providing shade and shelter for stock, and fencing material and firewood for the farm. Varieties he had been most successful with were sugar, red, and blue gums, Aleppo pines, swamp oaks of New South Wales, pepper trees, and white cedars. The remarkable pine and the Tasmanian blue gum did well for four or five years, and then died out. In preparing the ground he ploughed to a depth of 6in. to 8in. with a single-furrow plough, and cultivated thoroughly. At the time of planting he rooted the ground up well with a digging fork. He had had no success in planting trees in holes. The best time to plant was early winter—for pines it was the only time. The object was to get the trees nicely established before summer. Sugar gums and peppers, which were subject to frosts, were protected with super. bags, cut into halves, and kept in position with stakes. The secret of success was loosening the soil round the trees after each rain or watering. He advised farmers to fence their plantation sites before planting; to have the ground ready before procuring the trees; to plant in dull weather after rain, to spread the roots in four directions if possible, and press the earth firmly round them with the feet; to plant 10ft. apart, and to stake trees that required it. If watering became necessary it was a good plan to dig a basin round the tree, and fill with two buckets of water, refilling afterwards with the soil. A good discussion followed, and it was mentioned that large numbers of *Pinus insignis*, from 10 to 25 years old, had died during the dry spell.

**BEAUFORT**, April 29th.—Members remarked that crops last season had grown better on hard, drifted patches than on sandy soil. In reply to a question by Mr. G. Underwood, as to whether horses' feed should be damped, Mr. Mair advised damping the feed with a little molasses. The Chairman (Mr. Mugford) said he thought it well, when mixing chaff with bran or pollard, to wet the feed.

**BOOLEROO CENTRE, June 18th.**—Mr. E. J. Nettle read a paper from the *Journal* on "Blood Worms." Members discussed the subject, and emphasized the difficulty of distinguishing the symptoms.

**LEIGHTON, May 27th.**—**CO-OPERATION.**—Mr. J. M. McDonald delivered an address on this subject, giving attention to the purchase in bulk of super., &c., weighing of wheat, and the general need of a co-operative society. Discussion by members followed, and the proposals for co-operation were supported.

**MOUNT BRYAN EAST, May 22nd.**—**BARLEY SEEDING.**—The Chairman (Mr. J. Thomas) explained the manner in which he sowed barley for feed. After steeping for several hours, the barley was broadcasted on land that had been flooded about three weeks previously. The ground was dry to a depth of about 2in., and the barley was ploughed in to about 3in. below the surface. The barley came up eight or nine days after seeding, and was growing well. Papers on sheep and lucerne were also read, and the subjects were afterwards discussed by members.

**WHITE-YARCOWIE, May 29th.**—**CO-OPERATION.**—Mr. G. F. Jenkins read a paper which was given at last congress, and the matter was freely discussed by members. A committee was eventually appointed to secure further information, and report to the next meeting of the Branch.

## LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

**BLYTH** (Average annual rainfall, 16.46in.).

May 22nd.—Present: 12 members.

**FARM MANAGEMENT.**—Mr. W. Hutchens contributed a paper on this subject, in which he recommended farmers to pay attention to details connected with stables, stockyards, fences, gates, &c. He believed farmers should study books on carpentering and blacksmithing, as a knowledge of these subjects would enable them to make use of quantities of scrap material which always accumulated on a farm. They would be well advised to always have small stocks of split links, eyebolts, washers, bolts, and nails of various sizes; much annoying and often costly delay would be avoided by following this advice. He thought it wise to always carry a tool box when taking an implement out to the field. Ploughs, cultivators, and harrows should each be provided with swings and chains, so that time should not be wasted transferring them from one implement to another. Care should be taken with the implements and fittings to see that they were put away properly; if wooden parts were allowed to rest on the ground they would rapidly rot. When an implement was finished with for a season, it should be thoroughly overhauled, so that it would be ready for the next season's operations. All working harness should be thoroughly cleaned and oiled not less than twice a year; trap harness should be attended to frequently, as it was not so substantially constructed, and would perish in a very short time if not cared for. Every farmer should have a corner fenced off near his yards for a waste wire depot, to which all pieces of waste wire should be consigned. If these were allowed to lie about the fields, they would eventually cause trouble with various farm machinery. Mr. Harmer, who agreed with opinions expressed in the paper in every respect, said it was a great advantage to have an anvil on the farm. Mr. Deland also supported Mr. Hutchens's paper, particularly in regard to the suggestion as to overcoming the difficulty with odd bits of wire. Messrs. Wiltshire, H. W. and W. O. Eime also commented on the paper.

**CLARE** (Average annual rainfall, 24.30in.).

May 28th.—Present: 20 members.

**WINE GRAPES.**—A paper on this subject by Mr. J. H. Knappstein, was read as follows:—"The growing of wine grapes in this district has been carried on successfully for many years, and some of our older vineyards that were planted over 50 years ago and more are still as vigorous as ever, and according to the treatment received, bear as heavy crops, and are of as good a quality as any grown in

South Australia. The reason of this pursuit not having extended as it should have done is therefore not attributable to the unsuitability of the district, but is regulated by other factors. Some 20 years ago the planting of wine grapes was boomed by certain interested parties, and every effort was made to induce the planting of wine grapes suitable for the production of heavy export wines, for which an almost unlimited demand at remunerative prices was predicted. The efforts were successful in so far that a fairly large area was planted, and on coming into bearing the stocks of wine increased everywhere, but the demand showed no corresponding increase, whereas the buying firms reduced the quotes to a figure not covering cost of production to the wine-maker. For several years the industry passed through a severe crisis, everyone connected with it, from the grower to the maker, losing considerably, until this very desperate state of affairs brought about its own remedy, by finding other outlets for the production of wine-grapes. In the first place the Federation of the States under the Commonwealth broke down the barrier of duties, and a very much larger demand was created, and is still growing rapidly in Australia. The distillation of wine for brandy and other purposes also helped to reduce surplus stocks, and at the present moment distilleries alone take nearly half the production of all the vineyards in Australia. The dried fruits industry is responsible for the re-grafting of many acres of wine grapes to other varieties more suitable for drying, and the result has been a remarkable prosperity for a number of years to these growers, until it would appear now that the production of dried fruits is, or has, overtaken the demand in Australia, and the surplus thus created is again coming back to the wine cellars. The demand for wine for Great Britain has kept steadily on about the same level, the last two years showing a somewhat increased quantity being shipped, and during the past 12 months a still further improvement has been shown. The position is at present that with increased demand everywhere, we are confident that judicious planting of the right sorts combined with good cultivation must be to our advantage. One of the essential factors for consideration in laying out a vineyard is the deep breaking up of the soil, to give the roots plenty of scope, which unfortunately in the past has not been done very thoroughly. Grape vines are about the hardest plant in cultivation, and when during the last disastrous drought the greater portion of other plant life has failed in producing any crop at all, the grape vines, although suffering to a great extent, have not died out, and produced a light crop of excellent grapes. In fact, in some vineyards where extra good and deep cultivation was practised, the crops have reached 75 per cent. of the normal. Hundreds of acres of grape vines have been planted in this district on a first ploughing of from five to six inches, some even less, and the vines in ordinary seasons have flourished and produced fair crops, but I am confident, with a 9in. to 10in. ploughing, or better still, a subsoiling, the results would have shown to much greater advantage. We have an object lesson in Victoria, where the new plantations on phylloxera-resistant-grafted stocks, are on subsoiled or trenched ground, and the difference between these and the older vineyards is remarkable. The varieties of grapes most suitable for wine-making have been tested pretty conclusively, and we now know which are the best. For the production of red wine the grape known as Shiraz is undoubtedly the king of all in quality. It yields well in ordinary good soil, and is free from disease, is a consistent cropper, and there is never any fear of any winemaker refusing to handle this grape. It is naturally a trailer, and the very best results are obtained on trellis, but it can also be profitably grown on the bush system, that is, with rod pruning, with the rods tied down to the trunk. For somewhat poorer ground Mataro and Greenache are the most prolific, and if the price obtained for them is somewhat lower, it is very frequently made up by the heavier yield. We have also the Cabernet Sauvignon, a grape of the very highest quality, but rather a light bearer, and it has to be trellised. The Malbec grape in some situations is a very heavy cropper, and of a quality between Shiraz and Mataro, but is not so consistent in bearing, and unless one is certain that a particular location suits it, it could not be recommended. There are dozens of other black grapes for wine making, but the above are well adapted for this district. In the white grapes, the Reisling stands out as the best. It is a fairly consistent heavy cropper, and proves best on trellis. The Pedro Ximenes white grape is highly spoken of as of good quality and a good bearer, but the writer has no personal experience of it under bearing conditions. Forsweet wine we can recommend the Frontignac and Malaga. The first, well known as a table grape as well, grows on the bush system, and is a very heavy cropper, but in

wet situations is susceptible to oidium. The Malaga makes a beautiful sweet wine of good character, and a lovely color, and seems to do extraordinarily well in the only one vineyard in this district where it is grown. The Doradillo grape is not to be despised for a light dry wine, while if distilled for brandy making it is the very best for quality, while probably no other grape can approach it for heavy yields. Many more good varieties of grapes could be given, but the above will give ample selection for all purposes. There may be some who would try a plot of a few acres of wine grapes this season, when it is impossible to procure rooted vines, and the least expensive way to establish a vineyard is to start with cuttings, of course on deep ploughed and well cultivated land only, and plant out two cuttings in each spot where the vine is to remain. With the present soaking rains there is every probability of both striking root, when one could be removed, as weather seldom kills a vine once rooted; and a rooted vine remaining in the same place without being transplanted is quite as good, if not better, than a two-year-old young vine transplanted. Some beginners find it very difficult at planting time to keep the lines straight, and after a lot of measuring and running about the result is disappointing. I find the simplest and most satisfactory way is by sights, that is, supposing one desires to plant a block of, say 10 acres, it is necessary to mark the outside line straight, and put a sight stick at each 10ft., or whatever distance one determines to plant, and another row of 10ft. sight sticks at 10ft. distance from the first, running parallel with the first line. When these two sticks are up, the responsible party should go well back and get an assistant to put up another sight stick in line with the first two, outside of the block to be planted, and if the first two measurements are correct the outside sticks will also be 10ft. apart, and this will give the line one way. The same is done on the side line; but here one needs to be particularly careful that the angle is exactly a right angle, and if this is obtained the lines both ways are bound to be right. Now, having sights both ways, one man can mark each hole at the intersection of these sights with a spade, or make any other mark, and the planters can go ahead without troubling whether they are in line. When planting with a 10-ft. stick, or even with a line a chain or more long with marks at every 10ft., the line does not allow for the undulations of the ground and becomes curved, whereas with using the sights only the vines may be an inch or more than the 10ft. apart, but the rows are straight and easier to cultivate. When planting vines, not intended to be trellised, the distance of 10ft. apart each way proves the best for cross cultivation, but if the vines are to be trellised the rows could be 12ft. apart, and the vines in each row 8ft. apart, which would take about the same number of plants per acre, but will give 12ft. in width for ploughing, and will take less posts and wire for the work. The wine industry now appears to be on a sound footing, and there is every prospect of further improvement in the demand, and any part of a holding however small and steep can be planted, and the work entailed in cultivating and picking grapes does not interfere with other operations. It is therefore well worth the consideration of every landholder in this district to plant at least a few acres of wine grapes, and he will be agreeably surprised at the result of his operations, and will avoid the danger of devoting the whole of his attention to one kind of crop only." In reply to Mr. Seales Mr. Knappstein said it was advisable to plant the heavier bearing varieties, such as Mataro, on the light, shallow soils. Mr. Dux asked if it was advisable to turn the clay on to the surface when ploughing deeply to plant a vineyard. Mr. Knappstein said it was not advisable, but the ground should be subsoiled to a depth of nothing less than 10in. Mr. Elliott wanted to know if it was advisable to subsoil with the aid of dynamite. Mr. Knappstein said that he had had no experience with that method, but thought it was a good way; it could be done for about £4 10s. per acre by that method. Mr. Angus (a visitor) stated that the concensus of opinion with regard to subsoiling with dynamite was that it was beneficial when only small charges of explosives were used and the soil was absolutely dry; it was no good if the ground was damp. Mr. Elliott asked if it was advisable to leave rods on the vines this year if they were badly affected by the drought. Mr. Knappstein said, providing it was not going to give the vines too much to do, and if there was suitable wood, he should advise leaving a few rods. Mr. Nolan said he could bear out what Mr. Knappstein had said in relation to planting a vineyard with cuttings, and gave an instance of how he had some years previously planted cuttings in his vineyard, putting them in 15in. deep, and he got 100 per cent. to take.

## GAWLER RIVER (Average annual rainfall, 17in. to 18in.).

May 26th.—Present: 10 members and one visitor.

**THE ORANGE.**—Mr. A. M. Dawkins read the following paper on this subject:—  
 “A deep alluvial soil, with good drainage, constitutes the ideal soil for orange-growing, but this fruit will thrive on loam, sandy loam, and sandy soil, with plenty of vegetable and mineral fertilisers. Stiff clay land, however, is unsuitable. The most favorable situations are the coastal districts and plains. Orange-growing is not a success in the hills or in localities subject to very severe frosts. Shelter from bleak weather is essential. The orange may be grown from seed, but the Seville stocks are preferred; being hardier and less subject to collar rot. The seeds are sown in the nursery in a specially prepared bed. They are sown broadcast, and covered with about lin. of loose compost. A screen of calico is erected over these beds as protection against excessive rain, heat, and frost. The seeds are sown in spring, and about a year later the seedlings are transplanted to the nursery bed. Some may be budded the same summer or early in autumn, but the tops are not cut off until the following spring. A few may be ready to transplant into the orchard the following autumn, but the majority will not be ready until the next spring time, or three years from the sowing of the seed. It is more economical for the gardener to purchase trees from a reliable nurseryman than to attempt to grow his own. Orange trees are planted at various distances apart, some growers putting them in as close as 15ft. x 15ft., others 25ft. x 25ft. The distance depends a good deal upon the soil and situation. A very rich deep fertile soil will grow larger trees than a poorer soil, and requires fewer trees to the acre. A fair average distance is 20ft. x 20ft. This allows for 100 trees to the acre, and if the soil is free, the roots will reach from one row to the other. I prefer planting the trees in square formation, as it is more convenient for working with the horse both ways between the trees. In planting, I find it best to use lines, putting six or more the full length, and using one in an opposite direction, and planting where the lines meet. Orange trees should not be planted deeper than they were in the nursery; in fact it is better to have the tree an inch or two above the level of the surrounding land to prevent the water, after irrigating or heavy rain, lying around the trunks. The young trees should be lifted with a good ball of earth around the roots. This prevents the shock of transplanting affecting them to any marked degree. Holes should be dug some weeks before planting, or the land should be subsoiled. Holes should be filled with suitable soil (sand and loam for preference) to within 6in. of the top, and then filled with water; this allows the soil to settle down, and avoids the shifting of the trees after planting. As the trees are planted the ground should be pressed firmly around them. They should be given a bucket of water, and mulched with a few forkfuls of half-decayed straw or other suitable material. This is one of the best means of helping a young tree through its first year in the orchard. The orange orchard requires careful cultivation not only to kill the weeds, but also to keep the soil open and loose. In an ordinary season the orchard should be ploughed four times. In May or June the soil is ploughed away from the trees on both sides. This leaves the tree with an open furrow on each side of it, thus draining off heavy winter rains. In the spring, September and October, these furrows are ploughed back and followed later with a good scarifying. After every rain through the summer the garden should be worked up with the scarifier. In seasons like the last two, all the work can be done with the scarifier. Unless the soil is naturally rich and loose and replenished every few years by silt from floods, the trees require heavy applications of manure. Manuring must accompany irrigation. A supply of humus is necessary to keep the soil open and loose, and help to retain the moisture, also to prevent the soil becoming cold and sour. For this reason a good supply of farmyard manure is essential to secure good results. It keeps the ferment of the soil healthy and active. If sufficient water is available the ploughing in of a catch crop such as peas or clover, can be practised with profit. Both farmyard manure and cover crops need to be supplemented with the use of commercial fertilizers. I recommend 2lbs. to 4lbs. of superphosphate, and 1lb. to 2lbs. dried blood per tree, and where necessary the addition of 1lb. to 2lbs. sulphate of potash per tree. A tree looking a little sickly with yellow-colored foliage and scanty and light, dry fruit, indicates a probable lack of nitrogen, and the application of dried blood will effect an improvement. Too much nitrogen will cause rough-skinned fruit. Superphosphate acts on the general vigor of the tree, increasing its growth and development. Unless a plentiful supply of water

of a good quality is available, orange trees cannot be grown profitably. Lack of water is fatal to the quality of the fruit. Trees must be kept continually growing if the fruit is to be of a high quality. Orange trees start to make root growth in July, and should the weather in that month and August be dry, the trees will need irrigating, or the fine fibrous roots will perish, and the effect will be shown later by the absence of young growth after flowering. If dry weather with fierce hot winds is experienced in November and December, the trees must be watered, or all exposed fruit will drop off. If the weather has been very hot and dry, trees that have been watered may lose a quantity of fruit, but they will certainly be better than those which are neglected. In watering orange trees it is necessary to give them a good soaking. Do not administer frequent and scanty waterings. An orange tree of an average age requires from 300galls. to 500galls. every three or four weeks, according to the conditions of the weather and the retentive power of the soil. After every watering, as soon as the ground is workable, it must be cultivated. On no account must the ground be allowed to become dry and hard. The selection of varieties depends entirely on the conditions under which the trees are to be grown. The Washington Navel is one of the best, but to be successful it requires good soil and plenty of moisture. My experience is that it is the worst of all the oranges to drop its fruit. Of the common oranges the Sabina, Siletta, St. Michael, and Paramatta are good hardy market varieties; Maltese and Ruby, the Mediterranean Sweet, Compeoda, and Valencia late, make good useful late varieties. No orange equals the Mandarin for flavor; it is easy to peel and clean to handle. The Emperor is one of the best kinds, but for flavor Nohilis is to be preferred. Daney's is a splendid packing mandarin, almost scarlet in color, with a slight musk flavor. Beauty of Glen Retreat is another highly recommended mandarin. This fruit will not improve after it is ripe. Oranges should not be over ripe when picked, or the flavor will be lost, and the fruit be flat and insipid. Orange trees are subject to the attacks of scales, aphides, and mites. The red scale has done much damage, and caused a lot of trouble and expense. The most successful remedy is to treat the trees with gas, putting a tent over the tree, and fumigating it. The black or olive scale is comparatively harmless. Its presence is accompanied by a soot-like deposit on the leaves and fruit. This is caused by the excreta of the scale insects, which drop on the leaves, and upon it a minute fungus flourishes, the remains of which form a black deposit. Spraying with kerosine emulsion, resin compound, or red spraying oil will kill the scale, and the black deposit will disappear. The cottony cushion scale is usually kept in check by its natural enemies, ladybirds, and it need cause no alarm. Orange aphides, which are much like cabbage blight, but black, attack the growing tips and flower buds of the orange, and if not checked will often interfere seriously with the flowering. Fortunately in this district they have many natural enemies—ladybirds, lace wing flies, and internal parasites. Spraying with tobacco wash or kerosine emulsion will destroy them, but in spraying be sure that the natural enemies of the aphides are not destroyed; if they are in evidence they will destroy the blight. Collar rot is troublesome in wet districts, especially if the soil contains a little too much clay."

#### NORTHFIELD (Average annual rainfall, 19in.).

May 4th.—Present: eight members.

HEADER V. STRIPPER OR HARVESTER.—In a paper on this question Mr. J. Williams said that he did not favor the use of the header. It was advocated on behalf of the header that the crop could be reaped before it was thoroughly ripe, and that loss by shaking was thereby avoided. He contended, however, that this practice was liable to result in the production of pinched grain. In his opinion, the crop should be quite ripe before harvesting was attempted, to ensure a sample of full, plump grain. In regard to the claim that the straw resulting from the header process was more readily eaten by stock than that reaped with harvester or stripper, his experience did not bear this out where care had been taken to reap the crop at the right period of its growth, and provided that the straw had not been damaged by rain. He admitted that in cases where a heavy crop was tangled and knocked down, there was an advantage in the use of the binder and header, provided the sheaves were tightly tied. There was considerably more work involved in the use of the header, and in many cases the threshing of the sheaves was not thoroughly executed. He believed the complete harvester was the most satisfactory and economical machine. In reply to Mr. D. Rowe, Mr. Williams

said that he did not think the stripper or harvester injured the grain, and he had never found that the header damaged the grain. Mr. E. W. Kelly had put through four and five loads of hay per day with the header. Mr. A. Low recalled the use of the steam thresher and cleaner favored in Scotland, and the beautiful samples of grain which were produced there. Mr. J. Dall, speaking from 20 years' experience, said the header was well adapted for use on small areas, more particularly for the production of good samples of seed wheat. Mr. Warden favored the harvester. Mr. Williams said that horses were unwilling to eat headed straw, and that they were only warranted in forcing the stock to eat it in a season like the past. Mixed with bran or molasses, however, straw made a good feed.

#### SADDLEWORTH (Average annual rainfall, 19.69in.).

April 16th.—Present: four members and three visitors.

DEMONSTRATION PLOTS.—Mr. F. H. Kelly tabled 26 varieties of wheats grown in plots, and harvested by his son Eric. The plots were 9ft. by 4ft. The seed was sown on May 23rd, 1914, and the crop was cut on November 18th. The rainfall was 10.28in. for the year, but only 5.18in. fell between seeding and harvest. Each grain was dibbed in 3in. apart, and 150lbs. super. was applied per acre. The plots when inspected by the Chairman and Secretary in the spring showed good growth for the season. The straw per acre is the gross return less the grain only:—Wheat per acre—King's Red, 23.28bush.; Bunyip, 23bush.; Thew, 22.50bush.; Own Selection No. 4, 22.22bush.; Golden Drop, 22.08; Own Selection No. 1, 21.30bush.; Red Tuscan, 20.52bush.; Late Glynas, 20.28bush.; Yandilla King, 20.21bush.; Marshall's No. 3, 20bush. Straw (Hay) per acre—Florence, 1 ton 2cwts. 74lbs.; Zealand Blue, 1 ton 2cwts. 31lbs.; Bobs, 1 ton 1cwt. 53lbs.; Thew, 1 ton; King's Red, 19cwts.; Marshall's No. 3, 18cwts. 54lbs.; Yandilla King, 18cwts. 53lbs.; Selection No. 4, 18cwts. 44lbs.; Firbank, 17cwts. 67lbs.; Bunyip, 17cwts. 24lbs. The yields from the other varieties ranged down to 10bush. and 10cwts. per acre.

#### SADDLEWORTH (Average annual rainfall, 19.69in.).

May 21st.—Present: nine members.

CURING BACON ON THE FARM.—Mr. W. Seales, in dealing with this subject, said the maintenance of a low temperature was essential to successful curing. The work, therefore, was best undertaken in the coldest months of the year. A cellar made a suitable curing room, as the temperature was less likely to vary than in other places, and as it was darker the meat was not so liable to lose its color. The principal ingredients used in preserving meat were salt, brown sugar, and saltpetre. A good brine for pickling was made as follows:—To 10galls. of clean rain-water add 15lbs. of fine salt, 10lbs. of coarse salt, 3lbs. of brown sugar, 1lb. of saltpetre, and  $\frac{1}{2}$ lb. of allspice. Dissolve the salt, sugar, and saltpetre in water, and immerse the allspice, tied up in a bag. Boil the mixture for one hour and skim off any frothy matter that rises to the surface during the boiling. The brine should only be made strong enough to float an egg or a potato. When dealing with thick flitches and hams it was a good practice to rub them briskly for the first two or three days. The salt should be pressed into every depression, cut surface, and joint. Clean pieces of hardwood previously soaked in brine, could be used as weights to keep the sides immersed. The meat should remain in the pickle for about three weeks. In dry curing he preferred using all fine dry salt, say 25lbs. to 3lbs. brown sugar, 1lb. of finely powdered saltpetre, and  $\frac{1}{2}$ lb. allspice. During the first three or four days this mixture should be rubbed over the fleshy parts and around the bones and joints. Afterwards the mixture should be spread over the sides about twice a week, allowing most on the ham and shoulders and less along the bellies. The sides should be stacked flesh up, one on top of the other, in such a position that when the salt dissolved it would run towards the thicker portions of the side and ham. The stacking should be alternated, so that the sides on top one day would be at the bottom the following day, and so on. From 15 to 21 days, according to size, would be sufficient time in the stack. There were several kinds of spices, that might be used for flavoring purposes, according to fancy, such as allspice, thyme, mint, sage, cloves, cayenne pepper, bay leaves, cinnamon, &c. When the salting process was completed the meat should be removed from the stack or barrel and placed on a table. All loose salt and bits of fat, &c., should be scraped off before washing it well with lukewarm

water and a little dissolved carbonate of soda. The bacon should be hung to dry in a room free from dust and insects. If the weather was unfavorable it might be necessary to dry it by means of heat from a dull fire. When it was sufficiently dry, if smoked bacon was preferred, it should be rubbed over lightly with olive oil. A simple way of getting the color and flavor of smoked bacon was to paint it over with "essence of smoke." In smoking care should be taken that as little heat as possible reached the meat that was hanging over the fire. This could be accomplished by placing sheets of galvanized iron on columns of bricks, thereby allowing the smoke to reach it in as cool a state as possible. After the desired coloring had been attained, and the meat had cooled down the bacon should be rubbed over again with olive oil, and hung up in a dry, dark room, taking care to exclude all insects. If a suitable room was not available the meat should be packed away in bran or coarse oatmeal or pea meal. Another good method was to saturate calico in a creamy solution of lime and water, and then closely stick the covering round the meat and hang it in a cool place.

BEAUFORT.—CORRECTION.—On page 909 of the May issue, Mr. Sampson is reported to have stated, "He favored a motor for working and pulling farm machines, etc." This should read, "He favored a small motor attached to the working gear of the harvester, for driving the machine, thus reducing the draught."

BLYTH, June 19th.—CO-OPERATION.—This subject was introduced and discussed. A motion that co-operation amongst farmers was not practicable, was carried.

LYNDOCH, June 24th.—Mr. G. W. Warren read a paper dealing with horses. The discussion was adjourned until the next meeting.

TWO WELLS.—Members, who discussed the papers on the subject of co-operation read at Congress, agreed that to do business through local committees would eventually mean that salaries would have to be paid; by this means any saving which might be otherwise effected would be absorbed.

WATERVALE, May 24th.—In reply to a question by Mr. Baker, members agreed that September and October were the best months to plant orange trees. Mr. Grace asked for advice regarding the best varieties of apples and peaches. It was considered that Brigg's Red May was the best early peach, and Lady Palmerston the best late variety. Mr. Burgess suggested Jonathan, Cleopatra, and Rome Beauty as the three best apple varieties. Mr. Grace preferred Dunn's Seedling. In reply to a query as to the best method of eradicating soursofs, members said constant working was the only means of contending with this pest.

## YORKE PENINSULA DISTRICT.

(TO BUTE.)

BUTE (Average annual rainfall, 15.42in.).

April 27th.—Present: 15 members and one visitor.

LESSONS FROM THE DROUGHT.—Mr. A. Schroeter read a short paper on this subject. He emphasised the necessity for fodder conservation in good seasons, and advocated binding and threshing portion of the crop and saving the straw. He recommended stacking some surplus hay in mice-proof sheds. He said a lesson could be learned from the farmers in the dry districts of Victoria, who stored oats in barns made of curved galvanized iron, in the same manner as a tank, but not soldered. The tanks were filled by means of an elevator, and were fitted with a spout at the bottom to fill the bags. A 2,000gall. tank would hold 250bush., and could be made in sizes to accommodate 1,000bush. As the tank was mice-proof, its cost was saved in bags in a few years. Messrs. W. J. Hall and W. Buchanan contributed to the discussion. Members generally considered that the header should be made greater use of in favorable districts.

**MINLATON** (Average annual rainfall, 17.46in.).

May 27th.—Present: 11 members.

**Co-operation.**—This subject was dealt with in a paper by Mr. J. McKenzie. He placed before members the advantages to be gained by a proper system of co-operation by farmers. The producing industry occupied such an important position in the welfare of the State that it was really incumbent upon farmers to organise, as only by that means would the best results be attained. Members agreed with the writer of the paper that co-operation was necessary. Mr. McKenzie drew members' attention to the fact that if super. bags were thoroughly washed immediately after emptying, they could be put to much further use. Mr. A. D. McKenzie said that he had tried washing super. bags in sea water, and had been so successful that he had been able to effect considerable economy in the purchase of sacks.

**YORKETOWN** (Average annual rainfall, 17.47in.).

May 15th.—Present: six members.

Mr. Davey read a paper entitled "Notes on the Past Season." He said that one of the peculiarities of the past season consisted in the fact that more than half the useful rain fell in the months of March, April, and the early part of May, as the result of which most of the early-sown crops gave returns varying from fair to good, whilst late-sown crops were extremely light. However, his experience of the past six years generally, had shown that late-sown crops gave the best yield of grain. Therefore, he said that it was not wise to adopt the practice which happened to be successful in one particular season. The yield of a crop depended a great deal on the conditions which obtained when growth commenced. In the past season, heavier applications of manure and thicker seeding, in the case of early sown crops, resulted in a better return than was the case with those sown later. Neither did he receive better returns from fallow than from stubble land. In a season like the last the main consideration seemed to be the time of seeding. He found that of King's Red, Federation, and Marshall's No. 3, the last-named variety had yielded the best. He wished to impress members with the necessity for making reserves of fodder, grain, as well as working capital in times of prosperity, to enable them to tide over the lean years. He thought farmers should make a practice of keeping two years' supply of hay on hand in all normal seasons, so that a stack should not be used until it had stood for 12 months. Some loss of weight would result, but he thought that this would be more than balanced by the increased feeding value, and the security against a crop failure. Extra quantities of grain, also, should be kept on hand for the purpose of feeding stock during the winter, if necessary, or in the event of a failure of crop it would be available for the following season's seeding. In any case, if care was taken, the seed could always be disposed of with very little loss. He maintained that every farmer, with the exception of those located in absolutely safe districts, should always have in hand for working capital an amount equal to two years' requirements. Owing to the irregularity of our seasons, it was necessary to make provision to meet conditions arising from droughts, and if producers were to recognise this, the prosperity of the country would be maintained on a better level. Discussion followed, and members agreed that farmers should save as much straw as possible in good seasons to be used in times of feed scarcity. One member thought stock preferred straw which had lain in the paddock for a time. Another member favored cutting the straw immediately after reaping, and chaffing it mixed with hay. Mr. Hartmann exhibited some fine Pinkeye potatoes grown with the aid of irrigation; also a tomato plant of unusual growth.

**WESTERN DISTRICT.****COORABIE** (Average annual rainfall, 11in. to 12in.).

May 1st.—Present: 12 members and four visitors.

**THE SELECTION AND CARE OF TEAMS ON THE FARM.**—Mr. E. J. Stretton read a paper on this subject. He said that the heavier types of horses were good animals, and served their purpose, particularly so when there was heavy work

to be done; but there was a great tendency at the present time to prefer the lighter types, mainly on account of feed. There were three essentials to look for in purchasing a horse, *i.e.*, soundness, strength, and stamina. He favored the short, nuggetty animal. It should be wide in the chest, short in the neck and back, deep in the fore and hind quarters, short and heavy in the legs, with plenty of hair and bone, and with a short, blocky head. As a rule this type possessed all the characteristics that made for the most useful animal on the farm. It was generally docile, and possessed great endurance, plenty of grit and energy, in addition to being a splendid doer, and having plenty of pace. It would do far more work than any other type on the same amount of feed, and kept in splendid condition whilst other horses fell away. On most farms there were to be found heavy horses, and medium and lighter sorts; therefore, in selecting teams for the different farm implements attention should be given to balance. Steady pacers should be selected for the heavy implements, and the faster animals for the drill. Where a scratch team was used for a long ploughing season it would be found at the finish that all the horses would be more knocked up than would be the case if an uniform team were used. The food ration should be varied according to circumstances, but only good wholesome food should be fed to horses. Attention should be given to harness. An ill-fitting collar would result in sore shoulders, and would often cause a horse to jib. When sore shoulders did occur they should be dressed with castor oil, and when the horse was again worked a false collar of some soft material should be provided. Stabling accommodation should never be neglected, as it had an important bearing on the well-being of the horse. Unnecessary harshness in the handling of the horse should always be avoided. In reply to questions, Mr. Stretton said that no one pure breed of horse fulfilled the requirements of their district, but the Suffolk Punch was the nearest approach. Horses should not be given access to water when unduly heated, but otherwise they could be allowed to drink at any time. To prevent sore shoulders Mr. Riddle recommended the clipping of the hair on the horses' shoulders where the collars rested. Mr. Wheaden thought thorough grooming was the best preventive measure. Mr. Stretton advised care in driving, especially in rough country, and said the pace of a horse largely depended on the way it was broken in. Members thought that when working a horse for the first time after a long spell the shoulders should be bathed several times with cold water.

ELBOW HILL (Average annual rainfall, 11in. to 12in.)

May 29th.—Present: 14 members and five visitors.

MODERN FARMING.—This subject was dealt with in an interesting manner by Mr. P. C. Wake. He said that despite the improvements made in machinery and the greater general agricultural knowledge the farmers were no better off than they had been in the previous drought. Some of them were going in for too large implements. The 10 furrow plough, for example, when the surface was uneven, did not half plough the land, and the result was a healthy crop of weeds instead of wheat. He liked the old three to four furrow ploughs with the large mould-boards. Success did not depend upon the amount of work accomplished, but upon the way it was done. There should be a place for everything, and everything should be in its place. On a thousand-acre farm he would place the homestead in the centre, and divide the land into four easily accessible paddocks. He advocated early fallowing and the use of the peg-top harrows, which penetrated deeply. Ploughed well, and thus harrowed, the land would not require cultivating to kill weeds until seeding time. The harvester was better than the stripper, and cocky chaff could be saved. When forced to feed working horses with cocky chaff, the necessary additions of bran and pollard made its cost equivalent to that of hay chaff at £10 per ton. Every farmer should keep from 100 to 200 sheep, which alone would return from £50 to £80 annually, besides providing home rations. Sheepskins should be stretched well and treated with weevil wash to preserve their quality. A couple of foals or more should be reared each season, mating the best mares with the best sires available. A good foal was worth feeding after weaning.

Cattle and pigs likewise provided a handy source of income, and fruit trees should be grown round the homestead to improve its appearance, and to provide supplies for the home. A good discussion followed. Mr. R. Ramsey agreed that large ploughs were a hindrance and not an improvement. Mr. A. O. Dawkins said that owing to the presence of stumps the use of scarifier harrows was necessary in the district. Mr. A. Chilman (Chairman) said that the use of large implements enabled the farmer to do more work at the right time with less hands. The Secretary (Mr. G. T. Wake), and Messrs. E. Wake, W. G. Bradley, A. Tilley, and F. Frith also spoke.

**ADVANTAGES OF THE AGRICULTURAL BUREAU.**—Mr. E. Wheeler read a paper on this subject, in which he said every farmer should be a member of a Branch. Non-members claimed that they could grow as good crops as members, but they had selfishly been benefiting from the agricultural organization of the past quarter of a century. He thought the Branch should hold socials and homestead meetings periodically to encourage outsiders, create competition, and foster experimental work. Every farmer in the Commonwealth should do what he could to bring about a comprehensive system of co-operation, and it should be the aim of the Agricultural Bureau to afford practical encouragement and assistance. Messrs. Bradley, Dawkins, and the Secretary contributed to the discussion.

GOODE (Average annual rainfall, 12in. to 13in.).

May 26th.—Present: 10 members and two visitors.

**FARM ATTRACTIONS.**—The Hon. Secretary (Mr. W. Folland) read a paper on this subject. He said that farmers should do all in their power to make farm life as attractive as possible to the women and children. A buggy and pair, suitable for the womenfolk to drive, should be provided, to enable them to visit their friends quite independently of the men. Provision for outdoor games and exercises should also be made. An extract from the *Journal* on the same subject was read by Mr. W. G. Morcombe. Mr. L. Will emphasized the need of providing adequate lighting and ventilation in the kitchens, where their womenfolk had to spend so much of their time. Mr. N. Packer drew a comparison between the life of the young men in England and that of the youth of Australia. If more consideration were shown to the young men who undertook farm work, there would be no shortage of labor. Mr. Folland said that in cases where married men were employed on the farm, pieces of land should be apportioned to them, so that they could establish comfortable homes.

KOPPIO (Average annual rainfall, 22.40in.).

May 27th.—Present: five members.

**CARE OF EWES AND LAMBS.**—In a paper on this subject, Mr. C. Barraud compared the conditions under which sheep were kept in the United Kingdom with those obtaining in Australia. In his opinion farmers should exercise better supervision over ewes at lambing time than was the general practice here. A little assistance rendered to a ewe which was having difficulty in parturition might possibly be the means of saving both ewe and lamb. With this idea in view he recommended that ewes should be kept in a small paddock while lambing lasted, and should receive the attention of the farmer daily. They should be provided with good feed, calculated to promote a flow of milk sufficient for the needs of the lamb. Particular care in regard to feeding of the lambs after weaning was also necessary. This was the critical period in the growth of the lamb, and its importance should not be overlooked. He found that the Lincoln ram mated with the Merino ewe produced a superior lamb to that resulting from the Shropshire cross, as regards wool, frame and rapid development. Ewes of this cross mated with a pure Merino ram, also produced a good Comeback lamb, both in respect to wool and size of frame. Discussion by members followed, and all agreed that an early fodder crop was an essential to the welfare of ewes and lambs.

## KOONIBBA.

May 26th.—Present: 15 members and three visitors.

**FARM STABLES.**—In a paper on this subject, Mr. Koch said it was best to have one large building to include the stables, harness room, chaffroom, and a barn for wheat, oats, &c. With this idea in view he recommended a two-story building. A long wooden manger, running through the stable, with separate stalls for each horse, was most suitable, in his opinion. A watering trough should be provided in a handy position in the yard. Around this a stone wall should be built to protect the horses from the cold winds which prevailed in this district. Mr. Dohl preferred an earth floor for the stables, if the horses were not shod. The Chairman (Mr. Rudolph) recommended a floor made from sawn timber, while the Rev. Wiebusch suggested the use of trestle wood blocks grouted with concrete. Mr. Foggo said that the water trough should not be placed in the stable yard, as the water became dirty so quickly. Members preferred a strong slab fence to a stone wall for enclosing the stable yard.

## SALT CREEK.

May 22nd.—Present: 14 members and two visitors.

**LIME-BURNING.**—In contributing a paper on this topic, Mr. W. H. Stephens explained that there were several methods of burning limestone. The two principal methods, which he proposed to deal with in his paper, were burning on the surface, and burning in a kiln. The former method was, he considered, the best and easiest in country like theirs, where stumps were so plentiful. To burn a batch of from 150 to 180 bush, the bottom layer should be marked out with stumps in a circle about 5 yds. in diameter, two diameters, at right angles to one another, being formed with light brush. Stumps should be rested over the brush, so that when the kiln was lighted, a draught would be caused right through the kiln. The first layer of stumps should be 15 in. to 18 in. high, and care should be taken to see that all crevices were filled up. The first layer of stones should then be made from 6 in. to 8 in. in thickness. When making the second layer of stumps the radius should be about a foot less than the first, and the second layer of stone should be from 8 in. to 10 in. in height. This process should be repeated with alternate layers of wood and limestone, until the kiln was completed. For a kiln such as that described, 9 yds. to 10 yds. of stone, and about six good drayloads of stumps would be required. Two men should be able to build the kiln in about six hours. The kiln should be lighted in calm weather, in the evening preferably. If a strong wind should arise after the kiln was lighted, more wood should be fed to the side exposed to the wind. An excavated kiln should have a cross-section about 10 ft. square, and be about 7 ft. deep. This would contain very nearly the same quantity as the surface kiln. The bottom layer of stumps should be from 12 in. to 15 in. thick, and the first layer of stone from 3 in. to 6 in. thick. The remainder of the kiln should be filled with alternate layers of wood and stone, each from 10 in. to a foot in thickness, until the material was about a foot above the surface of the kiln. A final covering of cocky chaff, about 9 in. in thickness, would be found to effectively keep the heat confined to the kiln. Provision for lighting the kiln should be made when it was being built by placing a hollow log or three pieces of split timber down the centre to the bottom layer. It was preferable to crack the stone in the kiln, to avoid waste. Lighting could be effected by pouring a bottle of kerosene down the hollow in the centre, and dropping down some burning material. Discussion followed, and the majority of members favored surface burning on account of easier handling of the lime after burning.

YABMANA (Average annual rainfall, 15.14 in.).

May 22nd.—Present: 13 members and two visitors.

**POULTRY BREEDING.**—In a paper dealing with this subject, Mr. G. Dorey said:—Fowlhouses should be built of galvanized iron, with as little wood as possible. Where it was essential to use wood, it should be on the outside, in order to provide

as little harbor for tick as possible. The houses should face the east, so that the fowls would get the early morning sun, should be dry and warm, well ventilated, but on no account draughty. The houses should be cleaned out every week and disinfected to prevent disease. A little fresh lime and sand placed on the floor kept it fresh. The water vessels should be kept in the shade, as the fowls needed plenty of fresh water during the warm weather. A little Epsom salts could be put in occasionally. For laying purposes only he recommended the White Leghorn. Silver and White Wyandottes, White and Black Orpingtons, Rhode Island Reds, Red Sussex, and Plymouth Rocks were very good layers, good table birds, and also very good for cross breeding with the White Leghorns. The Wyandotte was not a good mother, for the reason that it commenced to lay again when the brood was from four to six weeks old. Continuing, the paper read:—"The Faverolle is a new breed to this locality, I expect, but is a breed that is coming to the fore very quickly. This fowl originated in France, a country noted for its high-class table birds. Although bred for table purposes, it has been found by expert poultry men to be a prolific layer, more especially in winter. The progeny, too, are robust, quick in growth, and very fleshy, so that they make ideal market birds at a very early stage. We must always remember what we are aiming at when crossing laying and table birds. For egg-laying alone I should recommend the following first crosses—Minorea and Orpington, Minorea and Wyandotte, Minorea and Plymouth Rock, Leghorn and Houdan, Leghorn and Red Sussex. All these make excellent layers, are hardy, and do well with reasonable treatment. For table birds we must select the birds with that point in view. For spring chickens the following crosses are everything that can be desired—Faverolles and Orpingtons, Faverolles and Dorkings, Houdans and Orpingtons, and Red Sussex and Orpingtons. For table purposes alone I should recommend Red Sussex, Dorkings, and Orpingtons. It must be borne in mind that the cockerel used should be the lighter breed of the two. Thus when making a pen of Leghorns and Orpingtons, use the Leghorn cockerel and Orpington hen. If mated the other way, not only are the results less satisfactory, but much injury may be caused by the cockerel being far too heavy. On no account use a cross-bred cockerel, as no good can come of such a mating. Second crosses are to be obtained by running a pure-bred cockerel with first cross hens." In discussing the paper, members were unanimous in agreeing that poultry could be profitably kept on farms, as otherwise the food they consumed would probably be wasted. In reply to Mr. M. K. Frost, Mr. W. Dorey said that pure-bred fowls required no more attention than common barndoor fowls which were often met with on farms.

**CARROW, May 27th.—ANNUAL REPORT.**—The Hon. Secretary (Mr. T. Barr) presented the first annual report of the Branch. Since the first meeting of the Branch in May, 1914, considerable progress had been made, and the membership had increased from 13 to 24.

**MILTALIE, May 28th.—CO-OPERATION.**—Mr. H. R. Jacobs contributed a paper bearing on this subject. He said that producers should avail themselves of the opportunities the Bureau system offered in the direction of co-operation. Under the present conditions, all the salaries, expenses, and commission of the agents of the many firms with which farmers had to do business were debited to them. It appeared to him that if a co-operative system could be evolved all this expense could be avoided, and the cost of machinery, &c., which they purchased would be proportionately less. Members agreed that co-operation was advisable and practicable.

**YADNARIE, May 29th.—INJURIES CAUSED BY HARNESS.**—Mr. B. B. Crosby contributed a short paper on this subject. He emphasized the necessity for exercising care to prevent injuries which ill-fitting harness caused to the skin of the horse. Blisters and inflammation of the neck should be dressed with arnica lotion, which was prepared by mixing one fluid ounce of tincture of arnica with 15 fluid ounces of water. This lotion was very useful for application to sores and blisters. The fitting of the collar should also receive attention. Saddle galls could generally be obviated by slackening the girth when the rider dismounted.

## EASTERN DISTRICT.

## (EAST OF MOUNT LOFTY RANGES.)

## BORRIKA.

May 29th.—Present: 21 members and four visitors.

**MIXED FARMING.**—In a paper on this subject, Mr. Gray dwelt on the advantages of combining other branches of farming with wheatgrowing. As time went on, the land in their district would gradually become more settled and cleared, and he thought it would prove very suitable for the different branches of farming. He believed the rearing of horses could be carried on successfully and profitably. When a settler purchased his team, he should include a few good serviceable mares, he preferred medium to heavy draught. A stallion which possessed those desirable characteristics which might be lacking in the mares, should be used. Dairying operations would prove very profitable to a farmer who had plenty of assistance from members of his family. Lucerne could be grown with the aid of irrigation, and its use as a food was very valuable for stimulating butter production. He favored a cross breed between a Jersey and Shorthorn. The keeping of sheep, he was sure, would pay the farmer handsomely. They were not susceptible to the effects of sand like other animals, and would thrive under conditions which would probably prove fatal to cattle. There were ample opportunities for the profitable disposal of fat lambs, wool, and skins. Owing to the presence of wild dogs and foxes, it would be necessary to yard the sheep at night time, and there would, of course, be the additional expense of erecting sheep-proof fences, but he was sure this would be compensated for by the returns from the sheep. Sheep from the northern areas did not thrive in the mallee districts, but those from the South-East were more suited to the conditions. He recommended the purchase of good Merino rams to mate with the ewes. The farmer could, with advantage, keep poultry. When commencing operations, good classes of poultry should be secured from reliable breeders, and further requirements could be bred from them. For egg production, he favored White Leghorn fowls, and for table purposes the Black Orpington. Feeding was important; a variety of grain foods and an abundance of green stuff were essential to success. It was important, also that the fowls should be well housed to protect them from the severities of winter. A few pigs should always be kept, as they would fatten on such offal and refuse as were always available on a farm. He favored the Berkshire breed. They were hardy, and would be found to fatten quickly. A kitchen garden was also an important feature. Fruit and vegetables could be provided for household purposes, and thus contribute towards the independence of the farm. In the discussion which followed, Mr. Miell said he did not favor Merino sheep for country such as theirs. Mr. Weber, however, thought the most suitable type was a cross between a Merino ewe and a Lincoln ram.

## BRINKLEY.

May 29th.—Present: 12 members and two visitors.

**FALLOWING SCRUB LAND.**—Messrs S. White and H. D. Humphrey contributed a paper on this subject, in which they stated that farmers in new scrub areas had two great difficulties with which to contend—the strong growth of shoots and the tendency of the land, unless well worked, to become infested with weeds. Stubble land intended for fallow should be burnt off early in February; if the stubble was not thick enough to carry a fire, a fire rake should be employed. Where shoots were more than 12 months old, they should be slashed in the summer months, and either raked into rows and burnt, or gone over with the fire rake. On a good hot day most of them would burn, and a nice, clean field would result. They had found that fires on scrub land were very beneficial; not only did they clean the paddocks, but they were a great check to takeall. They strongly condemned the practice of ploughing in shoots. Whilst as a general rule the depth of ploughing should be left to the farmer's discretion, they advised ploughing to a depth of not more than 3in. in the hollows. Sandy patches might be ploughed a little deeper. Farmers should start as early as possible in order to conserve the moisture, harrowing immediately after ploughing, and then cross-harrowing. Owing to the light nature of the soil in their district a set of good heavy harrows was nearly

as good as a cultivator, and mulched the land down nicely. Cultivating should not be started till about the end of September, when all weeds pulled up would die off. Sheep should be put on the fallow whilst the harvest was being taken off, as they would pick off the weeds. A few old ewes could be fattened in this way, and would be of great value for rations. Two hundred acres of nice clean fallow would prove more profitable than twice that area roughly worked. They favored the disc cultivator as it worked better than a share plough in stony ground. Mr. E. Pearson disapproved of ploughing the sand to a greater depth than the hollows; he thought a depth of 3in. was sufficient anywhere; the rougher the sand was left the better, as when harrowed down, it was liable to drift. Mr. W. Humphrey found, on his farm, that deep ploughing was not beneficial. The fire-rake was of great benefit; it killed the shoots better than a clean burn, as they died off slowly and did not shoot again. Messrs. Schenscher and Wilhelm favored the share plough for fallowing. The stumps absorbed a large portion of the moisture that should go to feed the wheat. Members favored fallowing to a depth of 3in., and agreed that January and February were the best months for shoot cutting.

#### CLANFIELD (Average annual rainfall, 16in. to 17in.).

May 29th.—Present: seven members and one visitor.

CO-OPERATION.—Mr. Wilkins contributed a paper on this subject. Where the holdings were small and did not warrant the heavy outlay of a larger holding, he said, purchase by co-operation would be advantageous, but he did not favor the system of local co-operation as outlined by the Clare Branch. The success achieved by co-operative concerns in other countries was mainly due to the financial assistance which they had been able to render to the producers. In South Australia liberal aid in this direction was already provided for, so that the scope of the proposed co-operation would, in his opinion, be limited. Owing to the keen competition between manufacturing firms, also, very good terms were allowed for any purchases they had to make, and co-operation would not be any improvement on individual effort. In new country, changes in the ownership of land were frequent, and this would certainly complicate the question of liability for the purchases made under a system of local co-operation. Co-operation in the direction of horse-breeding, he considered, was an excellent idea, more particularly if a Government standard were established for stallions. Mr. Hayward also read a paper on the subject of local co-operation. He was afraid that the difficulties which were likely to arise would outweigh the advantages of such a system, more particularly in the newly-opened up areas. He believed that co-operation on a wider scale, however, would remedy some of the disadvantages under which they labored at present.

#### CLAYPAN BORE (Average annual rainfall, 16in. to 17in.).

May 31st.—Present: 10 members and three visitors.

SHEEP ON THE FARM.—In a paper on this subject, Mr. W. G. Webb emphasized the importance of associating the keeping of sheep with other farm operations. He recommended the purchase of six-tooth Merino ewes. If export lambs were desired, these ewes should be mated, in November or December, with Southdown rams. He suggested the sowing in say, April, of each year, of a paddock with an early wheat such as Gluyas. The ewes could be run in this paddock after lambing, and the lambs would be sufficiently developed for marketing by August or September, while the wheat could still be harvested. Messrs. Hill stated that they had found crossbred sheep preferable to Merinos. Mr. Robinson was of opinion that the growing of fodder crops for sheep would not be profitable. Mr. D. P. McCormack, however, believed that the district was particularly adapted to the growing of fodder crops, such as barley, rape, &c. Lucerne grown with wheat to be cut for hay, was a good catch crop, but it did not always prove a success. Many members considered that wild dogs were not nearly so numerous as generally believed, and they thought it would be quite safe to leave sheep out in the paddocks at night time. Mr. Colwill thought "cocky chaff" could be profitably fed to sheep in dry seasons. Mr. Robinson also spoke.

## COOMANDOOK (Average annual rainfall, 18.01in.).

May 29th.—Present: 17 members.

**DESTRUCTION OF RABBITS.**—In a paper on this topic, Mr. J. Eschener said poisoning was the most efficacious method of dealing with the rabbit pest. If the poisoning was to be carried out by means of bait-laying, then it must be done at a time when green feed was scarce, say, in February or March. Every care must, of course, be taken to see that no farm animals had access to the poison. It would probably be found more effective to lay the baits in a plough furrow, as the inquisitive tendencies of the rabbits would cause them to investigate the furrow, and find the baits sooner than they otherwise would. A good poison could be made by mixing a quantity of pollard and water to the consistency of paste, then adding strychnine and also a little sugar to sweeten the mixture. The pumping of poison fumes into the burrows would also be found very effective. All the exits of a burrow, with the exception of the one on which it was proposed to operate, should first be filled in, and the gas should then be forced into the remaining hole. Care should be taken to ensure that a sufficient quantity of gas was pumped into the warren, or the rabbits would escape. If it was desired to fill in the burrows, the openings should be excavated for a couple of feet and filled in with sand, making a fairly large mound on top of the burrow. This would prevent the rabbits from burrowing out, as any attempts to do this would be followed by a falling in of the sand. Discussion by members followed.

## FORSTER (Average annual rainfall, 10in. to 11in.).

May 29th.—Present: six members.

**FARM IMPLEMENTS.**—In a paper on this subject, Mr. W. Searle emphasized the necessity for having the best types of farm implements, also maintaining them in good working order. He said that a strong set of harrows was essential, and they should be manufactured of good steel, as they would not lose their shape so quickly as those made from soft iron, and they kept sharper longer, and were therefore capable of better work. The V-shaped cultivator was the best type for their country, and if the tines were kept sharpened, not only would the implement perform more satisfactory work, but the draught would be considerably lightened. It was most important that the seed drill and harvesting implements should be in excellent working condition. It was unprofitable to have a drill that did not sow the seed and manure evenly, or a stripper that did not gather all the crop.

**SYSTEM ON THE FARM.**—Mr. Hayman read an extract from the *Journal* on this subject. Mr. J. Searle said he did not favor having farm buildings located very closely to one another, as considerably more loss would then be incurred in case of an outbreak of fire. He preferred straw to galvanized iron for roofing stables. He recommended the roofing of haystacks with galvanized iron. Mr. W. Searle said that thatching was quite sufficient for sheaved hay, provided the stack was well built.

## GERANIUM (Average annual rainfall, 16in. to 17in.).

May 1st.—Present: 15 members and three visitors.

**FRUIT CULTURE.**—The Hon. Secretary (Mr. D. L. Lithgow), in dealing with this subject, said commercial orchards were out of the question in that district, but there was no reason why each farmer should not grow sufficient fruit for home requirements. Practically all the fruits generally grown could be successfully produced in the district with a little attention. He advised members to plant a few trees near the homestead or the windmill, where they would secure proper attention. For the reception of the trees he dug holes 2ft. deep and 3ft. in diameter, and as the soil was stiff, mixed with it a quantity of sand and a little well rotted manure. In planting the roots were well spread out, and after being firmly fixed and staked, the trees were watered, and some dry soil was spread over the surface to prevent evaporation. When the soil in the vicinity of the homestead was unsuitable, a sandy loamy slope with a clay subsoil should be selected. Twelve months before planting this should be cleared of stumps and roots, heavily dressed with stable manure, and broken up to a depth of 12in. to 18in. A wind break should also be planted. The trees should be

set 20ft. apart each way. Mr. Perrin agreed that most fruits would thrive, but said that small holes were as effective as large ones when planting out trees. Mr. Jacobs preferred subsoiling to deep ploughing. Messrs. Pannell and Richards also contributed to the discussion.

#### GERANIUM (Average annual rainfall, 16in. to 17in.).

May 29th.—Present: 18 members and three visitors.

**TREES ON THE FARM.**—In a paper on this subject, Mr. Griffen referred to the wisdom of allowing a compact clump of trees to remain on a holding that was being cleared. The amount of moisture that would be drawn from the soil by these would not be sufficient to affect a growing crop in a good season. Sandalwood trees, which were not shapely, could be lopped, which would cause the development of young shoots. They would then not only be ornamental, but provide feed for sheep in times of scarcity. Continuing, the paper read:—“Sugar gums make a fine avenue, as also do Remarkable pines, both of which thrive well in this district. To provide a better appearance and to throw more shade sugar gums should be lopped ere they grew too tall. If it is not intended to lop them, pines (Maritime or Aleppo), planted in a single row in front of them in an avenue will give a better appearance. Trees of this description should not be grown too near the house or other buildings, nor closer than  $1\frac{1}{2}$  chains to a garden. It would prove useful in years to come were farmers to set aside a portion of their holdings for the purpose of growing trees for timber. This could be done inexpensively, and where the natural timber on the farm is short, there would soon be plenty of grown timber available for fencing and other purposes. The common pine that grows in this district (not the scrub pines) are worth cultivating. Useful seed and fodder trees should also be planted. The last 12 months have taught many lessons, and the value of the carob and the tree lucerne should not be overlooked. Poultry will thrive on the tree lucerne seeds, and pigs will fatten on the beans of the carob. Tree lucerne makes a good hedge, but as it absorbs a great deal of moisture it is inadvisable to plant near a garden. Tamarisk is suitable for ornamental hedges, but when grown singly is apt to become very scraggy.” Mr. Perrin thought the growth of wattle for bark would prove unprofitable. In his opinion sugar gum timber was unsuitable for fencing posts. Mr. Jacobs said that if sugar gums were cut at the proper age and were well seasoned they would provide good posts. Mr. Richards believed that the growing of wattles of the proper variety would prove a profitable venture.

#### HALIDON.

May 26th.—Present: 11 members and one visitor.

**STOCKING A MALLEE FARM.**—The following paper was read by Mr. L. Rosser:—“First and foremost the farmer should choose his horses. The stamp of horse I prefer is an active medium draught, about 16 hands high. It should not be younger than four years, as a younger horse is very liable to knock up with constant hard work. It is advisable to secure two or three good up-standing mares for breeding purposes, as horses for the next few years are going to bring big figures. Apart from this, horses bred in the mallee always do better than those imported from other parts. Pure-bred cows are preferable to crossbreds. The Jersey is about as good a breed as one can get. These animals are of a docile nature, rich creamers, and give a fair quantity of milk. It is far better to pay a good price and secure one good cow than to buy two or three cheap and inferior ones. The Berkshire or Yorkshire is the best breed of pigs for a farm, as they are good doers, and fatten very quickly. If a man intends to go in for them on a large scale he should rear bacon pigs such as the Tamworths. Whether one intends to go in for layers or table poultry, the pure breeds are far superior to the common, everyday barndoorers. Turkeys do remarkably well in the mallee, but ducks or geese do not thrive under mallee conditions. I do not propose keeping sheep for at least four years after the farm has been taken up. Of course, if fodder crops, such as field peas, rape, &c., are grown, one can keep them from the commencement of farming operations. The crossbred will pay better than the Merino in this case. They fatten quickly, and are much larger framed than the Merinos. Cows, pigs, and poultry should not be kept to any great extent until

the farm can grow enough fodder to maintain them, as it is not profitable to purchase feed." Mr. Muecke thought Indian runner ducks would do well in the mallee. Several members thought three-year-old horses quite old enough to stand regular farm work, and advocated buying them at that age if procurable. Mr. Clark was doubtful whether it would pay to rear foals in the mallee until feed grew in their paddocks. Mr. Muecke thought stony country more suited for raising foals, and Mr. Weste thought "sand" would be a great menace to foals. Mr. Braithwaite thought Berkshire pigs bred for porkers would pay better than Tamworths bred for bacon. Mr. Weste thought dual-purpose breeds of cows such as the Holstein-Friesian, more suitable for a farm than the Jersey.

#### LAMEROO (Average annual rainfall, 16.55in.).

May 24th.—Present: 17 members.

**EXPERIMENTAL PLOTS.**—Mr. A. J. Koch reported the results of some experiments which he had carried out. Plots, each 1 acre in extent, and sown with Mar-shall's No. 3 wheat:—Plot No. 1, sown with 50lbs. mineral super., yield 40lbs.; Plot No. 2, sown with 50lbs. guano super., yield 40lbs.; Plot No. 3, sown without super. (seed unpickled), yield 40lbs.; Plot No. 4, sown with 90lbs. mineral super. (seed treated with Beatsall), yield 43lbs.; Plot No. 5, sown without super. (seed treated with Beatsall), yield 43lbs.

**GARDENING.**—Mr. Grigg read a paper on this topic. Garden seeds should be sown in prepared soil, containing plenty of well-rotted stable manure. Care should be taken to see that the seeds were not sown too deeply, and the seedling should be followed by a heavy watering. Cabbage and cauliflower plants should be 21in. apart in the rows, 24in. being allowed between each row. Lettuces might be planted somewhat more closely, say, 12in. between each row and 9in. between each plant. Carrots, parsnips, turnips, and beetroot should be sown in small drills, 10in. apart. The plants should afterwards be thinned out to 4in. apart. Leeks required rich soil and an abundance of water. The plants should be put in drills 4in. deep, and when they had made sufficient progress, the drills should be filled in. This resulted in the production of a nice white stalk. Celery required to be planted in a trench 6in. deep. The soil should be well manured, and the plants should be about 12in. apart. When the celery was about a foot high the trench should be filled in and soil firmly banked up around the plants, in order to insure the production of a good white stalk. If potatoes were planted in early spring, frosts would be avoided. He recommended the Pinkeye and Redskin varieties. Up-to-dates and Carmens were also good potatoes. The plants should not be closer to one another than 12in., and 21in. should be allowed between the rows. The soil should be banked up around the plants just before they commenced to flower. Rhubarb should be planted in trenches 3ft. deep, and heavily manured. The plants should be not less than 3ft. apart, and no sticks should be pulled until the second year after planting. Newman's and Burdett's were both good varieties.

#### MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

May 29th.—Present: 11 members and four visitors.

**CONSERVATION OF FODDER.**—Mr. A. Forbes contributed the following paper on this subject:—"We all know, to our sorrow, how the working horses, herds of cattle, and the flocks of sheep have been depleted by the lack of sufficient fodder to keep them alive, and the main question is, what are the best means of conserving sufficient fodder for use in the time of scarcity. In a district like this, our great mainstay is the cutting of sufficient hay, when the opportunity offers, to last over two seasons. I know many farmers do not like cutting down a nice crop of wheat which would yield 12bush. to 15bush. to the acre. I know it is almost imperative with many to get as much money at once out of the crop as they can to meet present liabilities, but to those who can afford it, I maintain that an extra 40 or 50 tons of hay on the farm are better than bank interest. As we know, every three or four years hay has a fair selling value, because there is generally a

shortage somewhere in the State. Then there is the saving of the straw to a greater extent than has been practised. If this were cut with the binder, as soon after reaping as possible, it would help the hay supply, as, by mixing with the hay chaff, it makes a very good fodder when horses are not working, or only doing light work. I am not a great believer in straw fodder, but a good supply of it this season would have been very acceptable to most farmers. Every farmer should have a stack or two of loose straw in the paddocks. This is good for the stock to nibble at, and provides shelter against a cold, rough night. If the stacks were built on some of the poorest land on the farm these would soon become the richest spots, as a result of the animal droppings, and the decay of the straw, and sufficient would soon accumulate to spread over a considerable area. Of cocky chaff every farmer should save a heap every year, as it is an invaluable standby, mixed with a little pollard or crushed corn. Ensilage also makes a good fodder, especially for milking cows. Perhaps it will be said that it is not possible to make ensilage in our district, as we do not grow enough fodder, but I know a few farmers in the north, who, when the seasons are favorable, always put down a pit, and they are always the last in the district to be out of feed, when the dry times come. This, of course, means an expense in constructing the pit, and labor in handling and chaffing up the green stuff, but the money and labor expended would soon be amply repaid. I would not recommend it for feeding to horses, except mixed with hay chaff. In the very near future, more attention will be given to the growing of summer crops. There are a great many grasses which have been proved by experiment to be, to a degree, drought resistant, and do not require a very great rainfall to keep them going once they are established, but, as I said before, our great mainstay is hay. We all know how easy it is to lull ourselves into a false sense of security by thinking we will never have bad seasons again, but if we are prepared for the drought, its effects will not be felt to such an extent as they otherwise would."

#### NETHERTON.

May 22nd.—Present: 10 members and three visitors.

CO-OPERATION AMONGST FARMERS.—In a paper dealing with this subject, Mr. A. Bald drew attention to the possibilities of co-operation between two or three farmers in their operations on the soil. In cases where a few farmers were settled close to one another, he considered there were ample opportunities for economy in time, labor, and capital, by mutual arrangement, more particularly at the busy periods of the year. It would be possible for them to purchase co-operatively implements and horses necessary for the cultivation of the total area of their farms. The idea might also be followed to the extent of lending one another assistance in the sowing and harvesting of their respective crops. Another phase of the matter was the economy which could be effected by the co-operative purchase of fertilisers, binder and sewing twine, and many other necessities. Members agreed that great benefits would accrue from co-operation on these lines in mallee country, where the farmer's capital was frequently limited. Mr. J. Donnell contributed a paper on "Seeding Operations," in which he advised members not to commence sowing before rain fell. In his opinion, seed which received a check soon after sowing never produced a first-class crop, even though later conditions were favorable. He recommended harrowing after drilling, and the use of high-grade superphosphate in quantities up to 90lbs. to the acre in their district. All shoots should be cut immediately after drilling, particularly in the case of fallow land, so that the crop might start under the most favorable circumstances.

PARILLA (Average annual rainfall, 16in. to 17in.).

May 28th.—Present: 15 members and three visitors.

SUBDIVISION OF A LARGE FARM.—In a paper on this subject, Mr. J. Northey said that, provided it was practicable, he thought the house should be situated in a central position on the farm, and with the outbuildings, stockyard, sheep yards, etc., should be contained in a square paddock of 15 or 20 acres. The farm should then be divided by two intersecting fences into four paddocks of equal area. He recommended a six-wire fence with iron standards and gum posts at intervals,

Where rabbits were prevalent, it was necessary, of course, to erect suitable wire-netting fencing. He thought that proper subdivision of the farm was so important that in some cases it would be wise to change the location of the house in order to bring about the desired arrangement. Mr. J. E. Gregory said that in country where there were big sandhills, it was better to have the house near the road, as loading was usually completed at the house, and the extra weight would not be added to the difficulties of carting over sandy land. Mr. M. Shannon suggested the subdivision of the farm into three parts for crop, fallow, and feed respectively, to be rotated from year to year. The three blocks should be again divided into smaller paddocks for the sake of convenience. Other members and visitors spoke, and generally agreed that a central position for the house on a farm was most desirable.

#### RENMARK (Average annual rainfall, 10.93in.).

May 6th.—Present: 10 members and one visitor.

**ORCHARD DRAINAGE.**—In an address on this subject, Mr. H. S. Pike said that no hard and fast rules for guidance in drainage could be laid down, but certain general principles might be considered. The first question that presented itself was, why should they drain land in Renmark? And the answer was (1) that because of seepage from the channels the land had become waterlogged; (2) because of surface salt; (3) to aerate and sweeten the land. The second reason was a very important one. Acid developed in waterlogged and salty land. Drainage pipes and the current of air flowing through them tended undoubtedly to sweeten the land. If settlers expected that surface salt would disappear from the ordinary action of drainage pipes they would find themselves mistaken. The pipes served to carry off the underground waters, and any injurious salts held in solution by them, but did not ordinarily affect the surface salt. The only way to get rid of the surface salt was by flooding, in conjunction with drains. On the Renmark 60-ft. land, where seepage was mostly met with, there was too much slope to allow of flooding, and the land generally sloped in two directions. In very wet seasons the rain reduced the salt content. This was especially noticeable after the heavy rains of three or four years ago. Those rains did a lot of damage, but they also did a lot of good by carrying the salt down. The dry and hot years latterly experienced had brought the salt to the surface, and it had been augmented by deposits from the bad water pumped during last season. The only way to get rid of the salt in this sloping country was to grade the land into level terraces. When the land was at its worst, seeped, and the surface in powder, if good water was available it should be flooded, when the surface salt would be dissolved and drained away through the underground pipes. The method was an expensive one, and in many cases it might not be thought worth while, but if the salt was plentiful and was allowed to remain on the surface it would kill everything except perhaps barley. And all the time water rates would be piling up on the land. In his judgment it was better to incur the expense than to let the land remain idle. In a piece of land of his own, apricots, which at first did well, had died off. Sultanas were planted where the apricots failed, and did well for years. But the sultanas were going off also, and he was now terracing the land. He was satisfied that it would have paid him better to have done this in the first instance. He intended to flood the land, and thought that one season would be sufficient to get rid of the salt from it. He was using double the usual number of drains in this particular piece of land, putting them only half a chain apart. The problem of dealing with waterlogged land was, as a rule, simpler. It was only a question of laying pipes correctly. It was essential that a well or other means of escape for the water should be provided before the pipes were put down. This preliminary provision had been neglected by many, to their sorrow. The handiest size for a well was 6ft. x 2ft., and it should be sunk to the river drift. This was generally encountered on the 60ft. level at from 20ft. to 40ft. down. He had known it to be struck at 17ft., but from 25ft. to 35ft. was more common. The depth varied in the most curious fashion. In one instance the shaft had to be sunk 24ft., while in another, on exactly the same level, and only four or five chains away, the drift was struck at 17ft. The well should be timbered from the top as it was sunk. Neglect of this precaution led to the abandonment of his first well at 6ft., owing to the inrush of slush and slime. The water was generally

found near the surface, with hard stuff below. In some cases a lot of trouble was experienced in getting a suitable shaft, and in some cases shafts had been sunk 40ft. without striking good drift. Mr. Basey suggested trial boring with an auger first, and Mr. Pike replied that he had not tried this himself, but he understood that a neighbor had done so, and had given it up. Mr. Basey had put down a number of bores lately in search of fresh water in pretty stiff land, and had experienced no trouble with the process. Two men had sunk 20ft. in a day in very difficult land, where the soil was much harder than on the 60ft., and they were only using a post-hole sinker. Similar bores had been put down in half the time by the means of a suitable auger. Continuing, Mr. Pike said that the surface sand on the 60ft. had a general depth of from 2ft. 6in. to 5ft. An alternative plan in a shaft was to run the drainage water into an open dam, if the situation was favorable. This had the advantage of giving a supply of water for stock and dip purposes. Or the water could be pumped out of the shaft. Some settlers were using their seepage waters in this way for vegetables, and the plan was answering very well, even although there was salt on the top of the land from which the water was drained. Mr. Nuthall remarked on the great variation in the effectiveness of well shafts. From some of them the water drained away very slowly, whereas others would dispose of an unlimited quantity in very quick time. Mr. Cole stated that he was watering vegetables by means of a pump on a drainage shaft. There was plenty of salt on the surface of the drained land, but the water was much fresher than that they were getting from the river. Mr. Pike preferred to put the main drain up the centre of the land, and to run the side drains into it, herringbone fashion. This was better than having the pipes straight down and across the land. More country was covered in this way and a better slope obtained. The depth at which the drains were laid was an important matter. They were often shallow, and should not be less than 4ft. 6in. or 5ft. below the surface. Under special circumstances he had put them down 6ft. Formerly, he had been accustomed to put them no lower than 3ft. 6in., as no seepage was in evidence below that depth, but he had found these pipes useless, except for surface water. Last year he had put some down 4ft. 6in., under the old pipes, and had found water coming in on all sides. Shallow drains were simply a waste of time. It was necessary to go right through the false subsoil. One man (Mr. Berriman) had found three layers of subsoil, and most of the water was under the third layer. In this case none of the drains were under 5ft. There was plenty of natural fall on the 60ft. country, but it was necessary to see that the bottom of the trench should be devoid of bumps and hollows. The pipes should be 3in., and it was necessary to start laying them from the well end. It was a great mistake to use 2in. pipes. They silted up much more quickly than the larger ones, and the difference in cost was not worth considering. The tiles should be laid end on end; a strip of paper over the joint would prevent loose sand from drifting in, and by the time the paper rotted the earth would be set. Pipes of different angles were now obtainable for joining the subsidiary lines to the main drain, and these were a great convenience, saving a lot of time in laying and keeping out the silt. The side lines should be run every chain, and for flooding every half chain. Three-inch pipes served for the mains as well as for the side lines. A useful plan was to have a piece of down-piping, let into the end of each line of tile, project about the ground. This would be found very handy for testing the different lines for blockage, as it was a simple matter by this means to flood each separate drain. Most growers ran the water straight into the well, but a lot of slush was washed into the shaft in this way, which tended to interfere with the getaway of water through the bottom drift. It was a good plan to provide a small catch pit above the well to catch the sediment. The water would run into the well over a board in the side of the pit, and the sediment could be easily cleaned from the pit. It was not safe to quote figures as to the cost of drainage, as this depended on so many circumstances—the depth of well, nature of ground, etc. In his own case two wells had cost him at the rate of 8s. a foot. Mildura tiles cost 16s. a hundred on the wharf. The general experience in sinking drains on the 60ft. was that after passing through sand a hard formation was encountered, with slush below it. Drain tiles were unprocureable from Mildura just now, but rather than delay, where drainage was necessary, it would pay to get tiles from Adelaide, though they would cost more. After a drain was opened up the pipes should be laid, and the earth filled in as soon as possible. Drains should not be opened up until the pipes were ready for it. If it were left open water

accumulated in it, the bottom got sloppy, and the pipes could not be made to lie level. If the drains were being made among trees much labor could be saved by the use of horses to fill in. The trench should be at once half filled by hand from the one side, and a two-horse scraper, with long chains, could be used for finishing off. The scraper was always kept on one side of the drain, and the horses on the other. The plan was not practicable among trellised vines. The preliminary filling in should be done very carefully. In reply to a question by Mr. Basey as to how one would know where to stop when running a drain up hill, Mr. Pike said he kept on going until the drain had got past signs of excessive water in the soil. The length of subsidiary drains depended on the fall. With a good fall two chains was a suitable length. At a depth of 4ft. 6in. or 5ft. there was not much risk of roots in the pipes. In reply to Mr. Nuthall, who said that the herringbone method of pipelaying was condemned by Bailey, Mr. Pike stated that he had found the system answer admirably. The side pipes should not enter the main drain opposite one another. He had tried growing mangolds to take the salt out of bad patches. They grew all right, but when fed to cows, caused diarrhoea. Members who had had experience with mangolds in Mildura salt land expressed surprise at this. Mr. Pike had had very little trouble with silt in the pipes. Mr. Berriman stated that Adelaide tiles cost £11 a thousand at Paringa. They were only half the thickness of the Mildura ones, but seemed stronger. He had had only six broken out of 1,000. Mr. Pike said that in the old days he had got pipes from Ballarat. They were thin, like those from Adelaide, but were warped all shapes.

#### SHERLOCK (Average annual rainfall, 14in. to 15in.).

June 5th.—Present: nine members and five visitors.

LUCERNE.—The Chairman (Mr. A. G. Schneider) delivered an address on the cultivation of this fodder. He recommended sowing in the early summer, in order to secure the advantage of both warmth and moisture. On heavy soil he approved of flooding the lucerne, but not in the case of sandy land. In the first year four or five good cuts should be obtained, and, later on, that number should be doubled. The closer the lucerne was cut to the ground, the better for the plant. For hay, he thought the lucerne should be left until half the crop was in bloom. He would sow the lucerne as a crop by itself in preference to putting it in with a cover crop.

EVENING PRIMROSE.—The Hon. Secretary (Mr. J. C. Genders) reported that Mr. G. G. Haekel, of Narrung, had stated in regard to this plant that the best results were to be obtained by cutting it with a mower about October or November, and distributing the dry and green plants on the land where it was desired to grow the plant. It then had the benefit of the summer heat, and a splendid germination would result after the first rain. It could also be sown successfully in February or March on well-tilled land or sandy soil. A good plan was to sow a small area of it, preserving it from stock and cutting and distributing it as described.

RECLAMATION OF SAND DRIFT.—A communication was received from Mr. W. E. Cross recommending the planting of blue lupine for the purpose of reclaiming sand drift.

QUESTION BOX.—*Pig Lice*.—The following emulsion was recommended for the eradication of this pest:—Dissolve ½lb. of hard soap in 2 quarts of boiling water, add 1 pint of kerosine, stir thoroughly, and add 3 quarts of water. Apply thoroughly with brush, cloth, or sponge all over the pig's body, repeating the treatment in about six days. Pigsties should be thoroughly cleaned and disinfected, and all bedding, &c., burnt.

#### TINTINARA (Average annual rainfall, 18.78in.).

May 29th.—Present: 14 members.

CONSERVATION OF FODDER.—Mr. M. F. Hodge read a paper on this subject, as follows:—“There have been many severe lessons learnt from the past drought. Hay should be the first consideration of all farmers in this district. Do not be afraid to use an extra bale of twine, as the surplus hay will always be one of the best assets. In my 10 years' experience in this district hay has never been below

**RAMCO, May 24th.—CO-OPERATION.**—A general discussion took place on this question. Members favored the idea, and it was thought they could co-operate in many directions to mutual advantage. Mr. Burnell introduced the question of pure-bred bulls for the district, and said he considered there was room for great improvement. It was resolved that further inquiries should be made into the matter. The matter of improvement in the breed of horses was also discussed. Members were of the opinion that it was more profitable for growers to buy than to breed.

## SOUTH AND HILLS DISTRICT.

**BLACKWOOD** (Average annual rainfall, 27in. to 29in.).

June 21st.—Present: 16 members and two visitors.

**FODDERS.**—Mr. W. L. Summers, in an address, compared the feeding value of different fodders with good, normal wheat chaff, and pointed out that hay cut in full bloom was of more value than when cut when the grain was ripe. Hay cut when the grain was fully ripe contained more indigestible matter in the straw than when cut earlier, and was equivalent to feeding straw and grain. It was essential to feed concentrated foods such as bran, oats, barley, and copra cake in small quantities with bulkier and less concentrated foodstuffs. In discussing the value of barley grown for hay, members thought that, if chaffed, the beard caused little or no damage to the horse's mouth. Mr. Turner stated that he had a small stack of barley hay and fed it as chaff; the horses liked it, and thrived on it.

**ORCHARD CULTIVATION.**—Members were of the opinion that the time to plough an orchard depended mainly upon the nature of the land, and the horse strength available. If practicable two ploughings were advisable; where one ploughing was given early cultivation of heavy land was not advisable, as the soil was liable to set down. In their district the most suitable time was to commence towards the end of July. Varied opinions were given on the value of double-furrow ploughs for orchards. Those members who had used double-furrow ploughs had replaced them with the single furrow implement.

**LONG PRUNING OF PEACHES.**—The Hon. Secretary (Mr. C. G. Savage) said the idea of pruning was to ensure that the trees should use the major portion of available food supplies in producing fruit, and yet maintain the vigor of the tree, as against the using of a large proportion of the sap in producing a superabundance of wood shoots. The leaders were not topped to a definite bud, but diverted to a lateral which was left uncut. The fruit shoots were left uncut where fruit was desired; other fruit shoots were suppressed, and from the base of these would spring shoots to bear the next year's crop. The pruning then consisted of cutting old and surplus fruit shoots and leaving new shoots uncut. On the Murray this system was succeeding, and at the Government Orchard, Adelaide, where the trees were irrigated, heavy crops of large-sized peaches were secured.

**GUMERACHA** (Average annual rainfall, 33.30in.).

April 26th.—Present: nine members.

**SMALL HOLDINGS.**—Mr. J. B. Randell delivered an address on "Small Holdings, and How to Make a Living From Them." He stated that agriculturists nowadays were faced with the problem of making their livings from much smaller holdings than those on which their forefathers worked, and it was therefore necessary for them to pay attention to intense culture and the utilisation of all available arable land. Fodders should be grown for their dairy stock, and also for fattening cattle, sheep, and pigs for market. It was necessary that they should adopt a sound system of rotation to counteract exhaustion of the soil. He believed that, instead of selling their produce straight off the land, it would be more profitable to feed the fodders and hay to their stock. He recommended farmers to keep only the best strains of stock; divide their holdings into various plots for the growth of hay, lucerne, mangolds, maize, peas, potatoes, onions, &c.,

thus growing sufficient fodder for all stock. Sheep were invaluable as a means of combating the growth of weeds, and improving the soil. Mr. B. Cornish thought that improvement of grass lands would be effected if they were broken up once every six or seven years. Mr. H. V. Cornish pointed out that a good water supply was essential for the practice of intense culture, and the distance from their holdings to the market and bad roads militated against the successful marketing of vegetables from their district. Mr. A. W. Cornish recommended the growth of kale, and suggested that the seed should first be sown in beds and planted out later. Mr. H. W. Norsworthy agreed that it would be necessary for them to practise intense culture, but he was of opinion that each farmer should specialise in some particular product. The fattening of stock for market was of considerable importance in view of the present state of the meat supply. Mr. A. Moore recommended improvement of grazing land and conservation of water.

HARTLEY (Average annual rainfall, 15in. to 16in.).

April 28th.—Present: 19 members and one visitor.

CO-OPERATION.—This subject was discussed, but members generally did not favor the proposals submitted.

CONSERVATION OF FODDER.—Mr. F. Bruus read a paper on this subject. He said the complete harvester was a great labor-saving machine, but owing to its use farmers had neglected to save the cocky chaff, which, during the past season, would have kept their stock economically, and would have saved the expense incurred in buying fodder at famine prices. The stripper should be used more and portion of the crop should be cut in the yellow-ripe stage with the binder and header. Headed straw chaff during the past season had been worth £7 per ton. He had found oat and barley stubble, cut with the binder immediately after stripping, to be valuable fodder. When stacking he carted two loads of hay to one of straw. Chaff made from the mixture was readily eaten by stock, and they thrived on it. Members generally agreed with the writer, but thought that the "golden" stage was rather advanced for cutting to secure the best-quality hay. Instead of using the header the cut could be chaffed, and the grain separated from the straw with the winnower. Mr. Bruus said the golden straw was useful for rough feeding; if cutting for hay he would use the binder at an earlier stage.

BUILDINGS ON THE FARM.—Mr. F. Pope made some practical suggestions. He advocated the use of stone for walls, and used as mortar about three parts of sand to one of pug, pointing up the surfaces with good mortar. Iron roofs were preferable to straw ones, which were liable to great risks from fire, and accommodated birds, mice, and snakes—to say nothing of the old hen.

HARTLEY (Average annual rainfall, 15in. to 16in.).

June 22nd.—Present: 10 members.

SAND-DRIFTS.—Mr. F. Hassam read a paper on this subject. He said the best way to recover sand-drifts was to cover them with stable manure, and drill in rye just before the first rain. It required about 20 drayloads of manure to the acre, so that this course was rather expensive. A less costly method was to drill in a mixture of rye and barley, say  $\frac{1}{2}$  bush. of each, together with 70lbs. of manure. This grew more quickly, and if the sand was not too loose, could be harvested. Care should be exercised, however, or the pressure of the wheels of the implements would cause the drifting to recommence. Primrose could advantageously be grown on drift areas. It required very little rain, and was a good summer fodder for cattle. Marram grass and Johnson grass were also useful; the latter was a good fodder, but difficult to establish, and very palatable to rabbits. It was not wise to allow sheep on bad drifts.

WASTERS ON THE FARM.—In a paper under this heading, Mr. B. Wundersitz urged the discarding of all useless and unprofitable stock. All cows should be tested, and those which were not up to a reasonable standard should be got rid of. Useless implements should also be discarded, and fences and gates which were not serviceable should be replaced. Members discussed the papers. In regard to testing of cows, it was thought that the churning of the milk was the most reliable method of determining its value.

MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).

May 25th.—Present: six members and two visitors.

**ROTATION OF CROPS.**—Mr. F. A. Wheaton, of the Redhill Branch, read the following paper on this subject:—"No hard and fast rule can be laid down for any particular locality; circumstances must always guide the practice to be followed. Nature has demonstrated to us in soils treated as permanent natural pastures that rotation is necessary. I have in mind such land, grasses rotated being barley grass, geranium, clover, and wild oats; not necessarily rotating every year. We take note of this, and carry into our agricultural practices such sciences as Nature shows us, and thus we find ourselves rotating our crops for the best results. Occasionally, however, we hear of results being achieved with continual cropping of the same crop year after year. In this connection I would instance Rothamsted Experimental Station, England, where, on some plots, wheat has been grown continuously since 1843; on liberally manured plots 35-40bush. per acre are still being harvested, and on unmanured plots up to 12bush. In South Australia, where conditions and soils are absolutely dissimilar, the following results were obtained at Roseworthy Experimental Farm during the years 1905-7 inclusive. The plot was dressed with 2cwt. super., ½cwt. NaNO<sub>3</sub> (sod. nitrate), and ½cwt. K<sub>2</sub>O. (potash)—1904, bare fallow; 1905, 30bush. 58lbs., 3 tons 4cwts. 67lbs.; 1906, 9bush. 22lbs., 1 ton 14cwts. 57lbs.; 1907, 4bush. 16lbs., 7cwt. 21lbs. To show that these results were not due to the season, the following results were contracted from other plots, as follows:—Wheat, after bare fallow, with 2cwt. super.—1906, 20bush. 48lbs., 2 tons 1cwt. 108lbs.; 1907, 20bush. 8lbs., 1 ton 17cwts. 98lbs. Experiments have clearly shown that the growing of wheat continually on the same soil is unprofitable, and this principle undoubtedly applies to all crops. The advantages of rotation are many. (1) Maintenance of fertility by keeping the soil in good mechanical condition. The tillage varies with the crop; some crops require deep working, others shallow; some crops are grazed, others carted off. (2) The periods of the year at which the crops are grown are not the same; consequently, as the nutriment of the soil gradually becomes available to plants there is less liability of waste and exhaustion. Some crops, such as wheat, lucerne, kale, &c., are deep feeders, while barley, turnips, &c., are shallow feeders. (3) The farmyard manure available, which supply is very limited, is used to better advantage. Root crops thrive on fresh organic matter, and the following cereal derives more benefit from the residue left by the root crop than from fresh manure. (4) When rotation is pursued, diseases do not present themselves so frequently. (5) More live stock can be kept on the farm. (6) Rotation of crops helps to solve labor difficulties. The work on the farm is distributed more evenly throughout the year. (7) When legumes are introduced the soil is enriched in its nitrogenous content. In older countries, rotations are more or less established. In newly settled districts the most advantageous rotations have to be determined as the land becomes more settled. In the Northern Areas of this State we find the simple rotation—bare fallow, wheat. In Lower Northern districts—bare fallow, wheat, barley or oats. In Middle Northern areas—bare fallow, wheat, pasture. Of course, the area in which barley or oats follow wheat is limited; where rainfall is deficient, bare fallow must precede the cereal for a successful crop. Lucerne is often sown with wheat as a catch crop. The hay is taken off the land in the early summer months, when the lucerne has free growth. Of course, the success of this crop is dependent on the summer rains; but if one successful crop out of three is secured, the practice is a profitable one. Systems of rotation on Kangaroo Island have yet to be established. Kangaroo Island soils are deficient in organic matter, and the best method of meeting this difficulty is to grow forage crops and feed them off with stock, especially sheep. The question then naturally arises—"Which crops are most suitable?" I prefer turnips, rape, and perhaps pease. Such crops as maize, sorghum, kale, &c., are rather heavy feeders, and Kangaroo Island soils do not seem equal to the demands. We are told that English farmers consider the turnip crop a success if the forage grown pays expenses, the manure left on the land being considered as the profit. This may well be borne in mind by our own farmers. I think it has been proved that wheat is not altogether successful as a first crop on new land. Oats or barley are more suitable. As the land becomes more worked

and aerated, and more humus is incorporated, conditions are more favorable to wheat. A rotation on the following lines may prove interesting—Oats, turnips, barley, pease or rape, and, as circumstances warranted, wheat substituted for oats; all of these crops have been grown more or less successfully on Kangaroo Island. It may be found that the soil cannot sustain this rotation, and bare fallow or pasture may have to be introduced. Kangaroo Island is as suitable for stock raising as cereal growing, and more forage crops should be grown. Objection will be raised, perhaps, in the direction of fencing. We know that this is a heavy initial outlay of money, as sheep require comparatively small fields, with good fences. Notwithstanding this fact, I think that to make farming operations pay, stock must be kept on the farm. Potatoes should also be more generally grown, as the potato market is always a payable one." Mr. Wiadrowski would not apply fresh stable manure to root crops, as it produced heavy foliage at the expense of the roots. In regard to potatoes, members agreed that grubs were the greatest trouble they had to contend with. The Chairman (Mr. R. Wheaton) advised the bagging of the crop immediately after lifting, care being taken to exclude the destructive moth. Filling the tops of the bags with sand had been found to assist in this.

#### MORPHETT VALE (Average annual rainfall, 23.32in.).

May 18th.—Present: eight members.

THE FARMER'S FLOCK.—Mr. H. N. Sprigg read a paper on this subject. He said the enormous depletion of stock, and especially of breeding females, had created a very serious position in Australia. Statistics showed that the flocks in the State had been reduced to the lowest level for 48 years. The highest figure reached was 7,600,000 in 1891, and the strength remained above the seven million mark till 1895, when it dropped to five million. There was a further reduction to 4,800,000 in 1902, but that was 600,000 better than the present position. The steadiness of the decline of late years was indicated by the fact that in 1908 the seven million mark was nearly reached. The problem now was how to increase the flocks and improve the lamb export trade in the shortest time in order to take the fullest advantages of the good seasons ahead, and the satisfactory prices that would rule. He suggested that the farmers should breed their own ewes, and in spite of high prices offered, should retain a large percentage of their ewe lambs. Under normal conditions there was more profit in purchasing ewes for breeding purposes. As it was the farmers' and lambgrowers' flocks had suffered the greatest losses. This was due to drouthy conditions, and the high price of meat. Lack of feed had forced the owners to market the saleable mutton, and they now had to replace the ewes. Unless ewe lambs were saved the breeding-up process would be slow. The first factor to be considered when breeding export lambs was the selection of a pure-bred ram suited to local conditions, and the farmer's fancy. His ideal breeding was large-framed, long-wool Merino first-cross ewes, with good constitutions, mated with a large-framed pure-bred ram of one of the English Down breeds. The purity and type of the ram should be above suspicion, and any extra expenditure incurred in his purchase would be returned many times in every 100 lambs. A good discussion followed.

#### MORPHETT VALE (Average annual rainfall, 23.32in.).

June 17th.—Present: six members.

PLANTING AND CARE OF VINES.—Mr. C. Kenihan read a paper on this topic. Land on which it was proposed to plant vines, he said, should be prepared by good, deep ploughing, and reduced to a fine tilth with the aid of harrows and roller. A length of fence wire should be strained up tightly over the line in which it was proposed to plant the vines. Pieces of tarred twine could be used to mark on the wire the positions of the vines. A crowbar was a suitable implement with which to make the holes for the vine cuttings; the holes should be about 1ft. deep. The cuttings should be placed in holes and surrounded with a pug made by mixing clay and water. This would keep the cuttings firm, and prevent the air from reaching the underground portions. The ground between the vines should be cultivated after every rain. For wine-making varieties he suggested planting Doradillo, Mataro,

Greenashe, Pedro's Shiraz, Carbanet; for currants, Gordo Blanco; for raisins, Sultana; and table grapes, Muscatel and Frontignac. In pruning, care should be taken not to leave too much wood, and also to cut the wood cleanly. For removing secondary arms and dead wood, the saw should be used. Water shoots and suckers should be cut off close to the stock. Members preferred planting cuttings to rooted vines. Mr. Kenihan was advised by members that the best time to roll a crop was at that stage of growth when the plants commenced to stool, but rolling should not be done if the ground was dry. Mr. Pocock had obtained excellent results from harrowing crops. Mr. Pocock informed members that he had successfully fed cows on melons cut up and mixed with bran.

#### MOUNT PLEASANT (Average annual rainfall, 26.87in.).

June 12th.—Present: seven members.

CO-OPERATION.—The Hon. Secretary (Mr. D. C. Maxwell) read a paper bearing on this question. Farmers had to pay over and above the actual cost of their purchases, the additional expense of the agents through whom they transacted their business, he said. The method proposed by the Clare Branch, however, did not provide a solution of the problem. The combination of a number of members of any Branch of the Bureau for the purpose of purchasing farm requisites, thus enabling a larger order to be given direct to a firm, was warranted, as they would no doubt secure their needs at a reduced figure in that way. The proposal that a committee of any particular Branch should act as a general agent for that Branch, he was afraid, would be doomed to failure. Very likely such a committee would be willing to act in that capacity for a while without looking for any reward; but if the business proved very considerable, he feared that they would be apt to forget the sentiment, and feel that they were doing other people's work for nothing. They all knew how useful the agents proved to be at times, and so long as they acted for a reasonable commission he could not see any objection to the system, and thought there was no necessity for the establishment of an Agricultural Bureau co-operative concern. Mr. Giles tabled a branch of apple tree in bloom, and asked whether members could supply an explanation. It was thought that the unreasonable weather was the cause of the tree flowering at that time of the year.

#### MYPONGA.

May 26th.—Present: 11 members.

CLEARING SCRUB LAND.—Mr. H. Pengilly read a paper on this subject. The first consideration, he said, was the nature of the scrub to be dealt with. In the case of bastard gum, he recommended ring-barking, and in the course of a few years it would be found an easy matter to remove the trees with the aid of a forest devil. The stumps should then be burnt. The method required perseverance, but he had found it very effective and economical, especially where the timber had been allowed to become very dry. For blue gum, sand gum, and red gum, he recommended mullenising, leaving a few of the best trees standing, as they became a valuable asset in later years. Honeysuckle, titree, and stringybark could be levelled with a scrub roller or log; later on it should be fired, and after a little picking up, would be ready for the plough. He recommended that, wherever possible, the wood should be carted and stacked for firewood. Mr. Sinclair said that bark-ringing should be done in February. Trees were then certain to die, and would not throw out shoots from the stumps. Mr. F. Muller said a very good method was to grub around the trees, leaving the roots exposed. It would be found that, in the course of a few weeks, the weather would cause a large proportion of the trees to fall.

#### NARRUNG (Average annual rainfall, 17in. to 18in.).

May 22nd.—Present: 13 members.

TELEGONY.—Mr. Hacket read a paper on this subject. He explained that the term was applied to the influence of a sire on the subsequent progeny of a dam served by other sires. He said that this theory of pre-saturation had received con-

sideration for some considerable time, and it was borne out by practical experience. He had noted cases where Merino ewes were sired by black-faced rams, and though these ewes were subsequently served by other rams, there were always a proportion of smutty-faced lambs among the progeny. He also instanced a number of similar cases with horses and cattle. He would not say that the theory of pre-saturation applied to every case, but he believed that it had a strong bearing on the progeny of some females. He concluded by emphasizing the care that was necessary in the selection of animals for breeding purposes. Members commented on the paper, and discussed the possibility of the effect which the care and feeding of a bull might have on the sex of his progeny, it being contended that when the bull was well fed, and paddocked away from the cows, the number of bull calves was greater than when the bull was allowed to run with the cows.

#### URAILDLA AND SUMMERTOWN (Average annual rainfall, 44.35in.).

May 26th.—Present: 12 members.

**CABBAGE GROWING.**—In a paper on this subject Mr. Kessell traced the history of the cabbage plant, and touched upon its feeding value. Lea land was very suitable for the growth of cabbages, he said, and heavy applications of phosphatic and nitrogenous manures were advisable. If it were intended to sow the seed in beds, the soil of the beds should be rich and friable, so that in transplanting the roots of the young plants should be injured as little as possible. Cabbages should always be planted in rows, as cultivation could then be practised much more readily. Varieties to be recommended to market gardeners were those which were most suitable for packing. Transplanting should be done on a dull, showery day. A space of 22in. to 24in. should be allowed between the rows, and the plants should be about 18in. apart. The holes should be made with a dibber, and care should be taken not to injure the plants when putting them in the ground. He found it good practice to dip the roots of the plants in a thick mixture of soil, lime, artificial manure and water. The ground should be firmly pressed around the stem when planting. Snails and slugs should be dusted with lime at night-time. Small green grubs and blight could be effectively dealt with by a spray of kerosine emulsion. No cure was known for club root, but when it occurred, spelling of the land should be resorted to. In the discussion which followed, Mr. Cobblestick said that cabbages required a large quantity of water to bring them to perfection. He had experimented with a mixture, in equal proportions, of salt and ammonia, and found that results were obtained which were as good as those resulting from an equal application of ammonia only. For late cabbages, the soil should be worked in the early summer, and plants should be put in at the end of January. He preferred applications of bonedust to ammonia, as the latter fertiliser, in his opinion, was inclined to make the plants soft and summer crops were more liable to club foot than early crops.

**CHERRY GARDENS, May 25th.**—There was a discussion on the rabbit. Mr. T. Jacobs said landholders, owing to dry seasons and the dearthness of meat, now had a most favorable opportunity of reducing this pest. It was essential, however, that they should keep pegging away with destructive measures.

**CLARENDON, April 26th.**—**BLOODWORMS.**—Mr. Harper mentioned that he had seen a large number of red worms, about  $\frac{1}{2}$ in. long and of the thickness of a thread, in the water trough at Happy valley, and expressed the opinion that horses became infected with bloodworms in this way. [Commenting on the above, the Government Veterinary Lecturer (Mr. F. E. Place, B.V.Sc., M.R.C.V.S.) says:—"The red worms about  $\frac{1}{2}$ in. long and as thick as a thread in numbers in the horse trough are, fortunately, not bloodworms. They are the larvæ of various gnats and similar insects. Mr. Harper is quite right in supposing that horses do get bloodworms from drinking troughs, but they are more insidious than those little red wrigglers, which are, fortunately, harmless to horses. The bloodworms are water white and almost microscopic, hence very difficult to detect; their growth to adult stage occurs after the horse has swallowed them. A practical way of getting rid of worms in a trough is to run the water nearly off and then flush it out with boiling water."—Ed.]

CLARENDON, May 24th.—Mr. Chas. H. Beaumont discoursed on the subject of his recent trip to England, and answered questions regarding conditions there compared with those existing in Australia, marketing of American and Australian apples, &c. In reply to a question from Mr. Harper, Mr. Beaumont said he would not advise the growing of nut fruits in preference to apples. The former were particularly subject to disease, and he strongly urged members to continue the production of apples, as being most suited to their district.

GUMERACHIA, May 31st.—CO-OPERATION.—This subject was introduced and discussed by members; it was unanimously decided to support the proposals of the Clare Branch in respect to the matter.

HARTLEY, June 23rd.—The evening was devoted to the "Question Box," and profitable discussions took place.

INMAN VALLEY, May 26th.—The Dairy Expert (Mr. P. H. Suter) gave a short address, in which he dealt with the economy of dairying. A lengthy address on various subjects was delivered by the Director of Agriculture (Prof. Arthur J. Perkins).

KANMANTOO, May 29th.—CO-OPERATION.—A discussion was initiated on this question. Mr. W. G. Mills considered that it would be necessary to have a store erected convenient to the railway station, for the purpose of storing goods as they arrived by rail, and thus avoiding demurrage charges. It was resolved that the delegates from the Branch should support the principle of co-operation at the next Congress.

LONGWOOD, May 29th.—In reply to a question asked by a member, Mr. Beythien said that cracked grain was not a good food for poultry, but if it were dry it would probably do little harm. However, if it should become damp, it was likely to become mouldy, and would cause injury or possibly death to the poultry to which it was fed. In reply to a question *re* seed potatoes, Mr. Roebuck advised members not to plant seed from unhealthy crops. In selecting seed only potatoes with good, strong shoots should be chosen; he emphasized the importance of using seed from only matured plants.

MOUNT PLEASANT, May 14th.—CO-OPERATION.—Mr. H. A. Giles read a paper in which he contended that if it were agreed that the adoption of the principle of co-operation would be of benefit to farmers, they would be wise to support existing concerns of a co-operative nature. Members generally agreed with the opinion of the writer of the paper.

STRATHALBYN, May 25th.—WHEAT.—Mr. Pyne, in a paper on this subject, dealt at length with the writings of Professor Cobb, of New South Wales. The consensus of opinion of members was in favor of sowing seed of a large and even type. The general opinion of members was that ploughing to a depth of 3 in., and in the case of fallow, 5 in., was most suitable for this district.

## SOUTH-EAST DISTRICT.

GLENCOE (Average annual rainfall, 33.84 in.).

May 31st.—Present: 11 members.

AFFORESTATION.—In a paper on this subject, Mr. G. E. Copping emphasized the importance of making provision for ample supplies of timber for the producing and manufacturing interests of the State. He thought that steps should be taken to maintain the supply of timber necessary for the manufacture of heavy vehicles. Trees greatly enhanced the value of farm property, and provided splendid shelter for stock. The value and uses to which timber was put did not seem to be generally recognised, and it should be realised that unless the forest areas were maintained and increased, there would be a serious shortage of wood in the near future. Discussion by members followed.

## KEITH (Average annual rainfall, 19.20in.).

May 29th.—Present: seven members.

**SHEEP ON THE FARM.**—Mr. J. B. Makin read the following paper on this subject:—"The Merino sheep are the most suitable for our rough country for wool growing. Large-framed ewes, with a dense and fair staple of wool, should be selected; they should not be wrinkly on the body. When selecting rams, choose small-headed sheep, also well covered with a dense and fair staple of wool, and a deep front with several folds; neither should they be too wrinkly on the body, as wrinkly sheep are more delicate and more difficult to fatten. All farmers should give their attention to fattening lambs. I would recommend Merino ewes and Shropshire or Lincoln rams, the latter preferably. I would suggest two lambings—first in May, and the second in August. The first lot could be fed on early-sown crops—oats or barley—then topped off on rape; the second lambing could be topped up on stubble and pea crops. I have carried out this system for several years with success. It would be wise for farmers to grow summer fodder for stock, also early winter crops, such as oats and barley or rye, and then rape and peas to follow, and also grasses. Rape and peas do well on our light sandy soil, also lucerne. Most of our well water is very suitable for irrigating the lucerne. All kinds of stock will for some time be very expensive and difficult to secure, and stock owners should take great care of what animals they have. The fly pest has been the means of destroying a number of sheep during the lambing seasons for many years past. This can be prevented by spraying with dipping solution just before the ewes commence to lamb. The crutch should be well smeared or sprayed right to the top of the tail. The dip should be made fairly strong—one packet should be sufficient to dip about 500 sheep. With a good race one man can do between 400 and 500 per day. I have carried out this system for several years, and have lost very few sheep with flies. It is much easier than crutching, and the ewes do not suffer to such an extent."

## MILLICENT (Average annual rainfall, 29.25in.).

May 11th.—Present: nine members.

**SEEDING.**—Mr. Holzgreffe advised members to get their crops in early. Mr. Fensom supported that advice. Mr. Mitchell asked if manure would detrimentally affect the seed when the ground was very dry. The Chairman (Mr. Mullins), said it had done so in his paddocks. Mr. Holzgreffe thought that it would in isolated cases, but not as a general rule. If the next season were dry, the late crops would be very short. This year all the early-sown crops had given the best results. On the Millicent flats they could always grow a payable crop. If he had land ready, well tilled, he would start seeding at once. It was impossible to make a hard and fast rule for everyone, but wherever there was green feed it was scarcely possible to plant too soon. In reply to a question Mr. Nitschke said the best way to wean a foal was to put it into a paddock where there was good green feed, and give it a feed of chaff once a day. A certain amount of dry feed was necessary, and a small bucketful of chaff every day was ample. Mr. Holzgreffe recommended keeping the foal in a stable for a day or two.

## MOUNT GAMBIER (Average annual rainfall, 32in.).

May 12th.—Present: 19 members.

**THE BACON PIG: HIS FEEDING AND CARE FROM BIRTH TO MATURITY,** was the subject of a paper written by Mr. P. C. Grace, of Warrnambool, which was read by Mr. J. Keegan. The writer said that at birth young pigs should be strong and lusty, and should average about 3lbs. in weight. The proper care of the mother for the first week was important, and would materially help to start the youngsters to robust life. "If the sow is in good condition," he said, "and she should be in much better condition than most breeders think, she will not require much feed for the first 48 hours. Naturally all sows are not alike in this. Some get very restless if they are kept hungry. Others will not get up from the farrowing bed unless made to. Some show symptoms of high fever and insatiable thirst. In such cases I have never found any ill effects from allowing a warm drink three hours after farrowing is completed (if the placenta has come away all right) and

if the sow comes looking for it. Warm water with a little scalded bran is suitable as a first drink. As the sow pulls round from her trouble, she will look for food. When she does this (usually, if all is right, in about eight hours from parturition) it will be quite safe to give her a sloppy feed. Keep milk out of the slop until the third day, making it fairly thin, using bran and pollard (chiefly bran) to thicken the slop. Do not give more than a gallon at a time, and feed two or three times a day, as she seems to need it. A full flow of milk may be expected with the sow about the third day, and she will from then on become more and more anxious for food. It will be quite safe now to gradually increase both quantity and quality of the food until at the end of about 10 days she is receiving just about as much as she will eat. Skimmed milk, bran, pollard, barley meal, and roots are all first class as foods for the sow, and she should have about 1½lbs. of grain per 100lbs. of her live weight from then on till weaning time. She should then wean her pigs at eight weeks old, and have lost little in condition while rearing them. Now to go back to the little pigs. A word or two on the care of them at first may be profitable. Most sows that overlie their pigs do so before they are three days old. To avoid this the piglets should be put into a box securely fastened into a corner of the farrowing sty, as soon as they are born. A gin case makes a very suitable box for the purpose, and it should have about an inch of well-broken soft straw in the bottom of it. It should have two or three boards nailed over the top to keep the young pigs from climbing out, but do not cover it at all closely, or the pigs may smother. For the first 24 hours the young pigs will need a drink from the dam every two hours throughout the day, and every three hours during the night. The second 24 hours they will be all right if fed at 2½ hours and 4 hours intervals. It is generally safe to leave them with the mother the third night, as few sows, unless deaf or exceedingly clumsy, overlie their youngsters after they are 2½ days old. If there is any doubt, put the pigs in the box while the sow is out feeding, and return them to her when she is comfortably settled down for the night. It may seem a lot of trouble to do this, but in reality it is not so; it only happens once in six months with each sow, and it pays. Nothing is more annoying to a pigraiser than to feed and care for a pregnant sow for four months, and to find her some morning with only two or three live pigs remaining out of a fine litter of 10 or 12. I guess he will do more worrying and cussing while feeding that sow till she has weaned those two or three pigs than he would have done over the work necessary to have given her a chance to rear the 10 or 12. During the first fortnight the young pigs will require no other nourishment than the mother's milk. They should then be about 8lbs. each, and be gaining about 6ozs. per day. If the sow has been fed in a broad, shallow trough, the young pigs will be learning to drink. As soon as they have learned, a small shallow trough should be put in a corner of the pen (hurdled off from the sow), and a little milk and pollard put in this at feed times. A very suitable mixture is 1lb. of pollard to 5lbs. of milk. Do not feed more than the little pigs will eat up clean. Should any be left from a previous feeding, clean out the trough into the sow's bucket and put a little fresh food in. Never top up old food. Always feed the little pigs first, or they will be sure to fill themselves at the sow's trough. (A shallow, wide trough is very important for the suckers, for if allowed to drink from a deep trough, many of them will have bad shaped backs, which no amount of feeding later on will hide.) Skimmed milk and pollard is the best food for young pigs, and the cheapest in most seasons. It is good practice to add a small amount of bone meal to the young pigs' food; about ¼oz. to each pound of grain used. This feeding will carry the pigs on till weaning, which should take place at about eight weeks. They should now weigh about 35lbs. each, and be able to get on all right without the mother's milk. They will, however, miss the shelter and warmth of her body, and if fed infrequently may suffer considerably from indigestion. Perhaps it would be quite safe to say that more pigs are ruined through lack of proper care and attention during the month or two succeeding weaning than from all other causes. They are allowed to lose their baby flesh, and either go back or stand still for a long time. They should for the first week be fed six times a day, and the food gradually thickened, until at 12 weeks they are getting a ration of 1lb. of grain to 4lbs. of skimmed milk, and receiving about 1½lbs. of grain per head daily, fed in four feeds. After 12 weeks, when they should be about 65lbs. live weight, they will start to move rapidly ahead, and will need more feed

week by week. It will not be wise to alter the consistency of the food until the pigs are near the ripening stage, about 21 weeks old. At 21 weeks they will probably weigh 150lbs., and should be gaining 10lbs. weekly. During the last three weeks the food should be just as thick as the pigs will eat. I find 1lb. of grain to 2½lbs. of skimmed milk quite thick enough, and that with as much of this as they will eat the pigs will gain 11lbs. a week, and be nice and ripe at 24 weeks of age. Pigs, of course, vary a good deal, but I am giving the average as found in practice here for some years past. A live weight of 180lbs. to 190lbs. is, if the pig is prime, the most suitable for making high-class bacon, and always brings the best price in the markets. Bringing pigs to maturity rapidly is a big factor towards success in pig-raising. They should never be allowed to stand still in growth. It takes about 1lb. of pollard or its equivalent per day, per 100lbs. live weight, to maintain a pig, i.e., to keep it from gaining or losing weight. The method of letting slips run about and pick up a precarious living for several months after weaning, as stores, is poor farming, and is both costly and unprofitable, as the daily maintenance ration goes on all the time. Again, the older the pig the more grain it will take to make 1lb. of gain. This is largely due to the great activity of the cell growth in the young pigs, and their wonderful powers of digestion and assimilation. We have found it takes on the average from 2lbs. in the very young pig to 5lbs. and even 6lbs. of grain in old back-fatters to produce 1lb. of gain. As a guide to the amount that pigs of various ages will require to produce the growths mentioned, pigs from 12 weeks to 16 weeks will need 2lbs. to 3½lbs. daily of pollard; from 16 weeks to 22 weeks, from 3½lbs. to 4½lbs.; and from then on till ripe, about 5½lbs. to 6lbs., which will be about as much as they will eat. The figures given above are not taken at random, but are the actual average figures obtained in a large number of experiments conducted by the writer during the last three years. It might be questioned whether in a season like this, with extreme prices ruling for all classes of grains and mill feeds, it would pay to feed on these lines. The price of a 180-lb. bacon pig—prime—is at present £4 10s. upwards—say, 6d. per pound live weight. Now the cost of producing a pig that weight, at normal feed prices, is about £1 5s. With us this season it costs about £2 15s. This leaves 35s. per head for feeding, commission, &c., and quite a fair margin for profit, though certainly not as much as in ordinary seasons. It must be clearly understood that these figures are for grain and milk only, the latter in very limited quantities. There are several things that never should be lost sight of in the raising and fattening of pigs. (1) Always work with good stock. The ill-bred, poor-quality pig is unprofitable in every season, and an absolute disaster in one like the present. (2) Always go round your pens first thing in the morning, and take particular note of the faeces from the pigs. These are quite the best guide as to their health. Such signs as drooping ears and tails and dejection, &c., often come too late to enable the feeder to treat a trouble successfully. In nearly all cases the faeces will indicate the presence of trouble. For instance, when pigs are sucking their dams, if their faeces are semi-liquid and grey it is a sure sign that the mother is getting either too much or too rich food. Cut down her grain ration a little, and miss a feed or two, and the trouble will most probably be stopped. Again, in the sties, constipation, as detected by the hardness and balling of the faeces, should have immediate attention, or serious loss will occur. Turn the pigs out for half a day, and let them nose about in the earth, miss a feed, and give them a liberal supply of bran in their slop. Personally, I rarely have any trouble with pigs from this complaint. I use bran in their ration always, using more or less, as indicated by the droppings. About 1lb. to 7lb. of pollard or other grain feeds is the average used. (3) See that the pigs are kept clean and comfortable, and not exposed to draughts, and do not let them sleep in dusty quarters. If you do the latter, lung trouble is almost certain to follow. Dust is a greater foe than even damp, where pigs are concerned, especially growing pigs. (4) Remember that once a pig gets a real check, it hardly ever pays to make a baconer of him. Sell him and let the other fellow try it. Re grain feeding experiments, we have found, in every case, pollard to be the cheapest and most satisfactory feed, pollard and peas next, then pollard and barley meal. As previously stated, bran is included in every ration, and a proportion of skimmed milk. If this is not obtainable, a slightly increased

amount of grain and decreased amount of water must take place. There is no doubt, however, that even a very little milk added to the ration for young pigs is of great benefit to them—much more so than its actual feeding value would indicate. During the last six months we have been working entirely without milk, and though not getting such satisfactory results as in the above records, we have made a good margin of profit, somewhere about 30s. per head."

#### MOUNT GAMBIER (Average annual rainfall, 32in.).

June 12th.—Present: 20 members.

**SUGAR BEET.**—Considerable discussion took place regarding the proposal to encourage the growth of sugar beet on a large scale in the district. Arrangements have been made for Victorian authorities on the question of sugar beet growing to attend at Mount Gambier and furnish information to members and others interested. Members thought that the first step would be to carry out experiments to test the suitability of their land for the growth of sugar beet. If indications were favorable the matter of erecting factories to treat the product could then be taken up. Mr. J. Holloway exhibited two samples of wheat, one of which was imported. The other sample was grown at Jeparit, on a rainfall of about 24in., and it was a better sample than the imported wheat.

#### NARACOOORTE (Average annual rainfall, 22.60in.).

May 8th.—Present: 18 members.

**DAIRYING.**—The Secretary read a paper on this subject, prepared by Mr. A. Pallant. The writer stated that the first essential to successful dairying was a good pasture of succulent natural grasses. Dandelion, geranium, and barley grass ranked high in feeding value for dairying. In ordinary seasons, with early rains, very little hand-feeding should be required, but in dry years fodder might mean a very large expense. For this reason it was well to make plenty of ensilage or grass hay each year for the dairy herd, as it kept the cows strong and in good, robust health, and what was not used in one year could be reserved for a time of scarcity of feed or a late season. Oats, wheat, or barley were excellent, but for firm, sweet butter, bran and chaff could not be surpassed. Lucerne, the king of all fodders, might give the milk or butter a strong flavor unless care was exercised in the feeding of it. Lucerne hay gave good results. Sorghum or maize, too, required care in feeding, or it might affect the health of the cows very seriously. The Milking Shorthorn was, in his opinion, the ideal dairy cow, being usually very docile and tractable, easy to keep, and of great milking capabilities, and if not needed in the milking herd was a valuable asset from a butcher's point of view. Many favored the Jersey breed, which, for quality of butter, certainly ranked first; but her temper was often at fault, and her disposition nervous, both serious items in a dairy cow, whilst for beef she was almost valueless, the flesh being dark and inferior, and the carcass small compared with the Shorthorn. March and April were perhaps the best months in the year for the cows to calve, as with the approach of winter better prices for butter ruled, and with early rains very little hand-feeding would be needed. However, while some cows would come in almost regularly, some would gain time, and others would lose, often by many months. Dairymen should test their cows' milk, or get the factory manager to do it for them. If they were not able to do either, by placing each cow's milk in turn in a pan, and letting it stand for 48 hours, they could ascertain the inferior butter cows. When the cows were brought in for milking they should be driven steadily, and dogs should not be permitted to worry them. If it was not intended that the cow should raise her calf it should be removed from her sight as soon as it could walk. The less she saw of her calf the less would the cow fret after it, and a fretting cow was not a profitable one. Heifers should be raised from the best cows. Dairymen should keep only the best they could secure, and keep on trying to improve that best. A bull should be obtained from a good reliable breeder, from one of his choicest milking strains, and should be typical of his breed, and of good constitution and color. Dry cows should be maintained in good healthy condition, so that they might calve under favorable circumstances.

Neither was it well to have them too fat. He thought all dairy cattle should be dehorned to prevent cows from injuring one another. Heifers that had been too much handled before calving were usually more difficult to deal with than the more timid ones, which, as a rule, yielded very quickly to proper treatment. It was very important to feed and milk the cows regularly. Cows with thieving propensities, hard milkers, or those with a habit of kicking should be handed over to the butcher as early as possible. If the kicking cow was a good one, a fresh milker should be tried. Often a cow would show a strong aversion to one individual, and at the same time display an equally strong affection for another. The milking yard should be located to allow of good drainage, and should be at a convenient distance from the separating room and dairy. The shed should be closed in on three sides, and the floor should be paved. No one with very uncertain temper should take up dairying as an occupation, as careful treatment and patience were essential to success. Learners should not be allowed to milk full milkers. It should be a strict rule that when the milking of a cow was commenced the work should not be interrupted until completed, otherwise loss would result. Separator milk should be fed to calves, pigs, and poultry. Care should be exercised to see that the separator was always running properly. Cream should be kept in a cool place, and, if possible, sent to the factory twice each week. It should never be sent to the factory in a sloppy state, as not infrequently it would arrive in a half-churned condition, and never under any circumstances should cold and warm cream be mixed together. Mr. Hart also read a paper on the same subject. He said that to be profitable, dairying must be carried out systematically. When they knew the difference between a profitable and an unprofitable cow they had taken a big step towards success. Some cows produced six or seven, or even 10 times as much as others, and until all the wasters had been thrown out dairying could not pay. If one cow produced 14lbs. of butter per week and another only produced 7lbs., they might think that one was worth two like the other, but supposing butter was worth 1s. per lb., and that it cost 6s. per week to milk and feed each cow, they would see that one cow returned a profit of 8s., while the other only returned 1s. It was not an easy matter to purchase a good herd of cows, but by selecting fair average cows or likely heifers, and by a strict system of weighing the milk, testing, and culling, every man could greatly improve his herd year after year, till he owned a really tip-top lot, but he should still continue to weigh, test, and condemn regardless of appearance. In his opinion, the best breeds were the Jersey, the Ayrshire, the Holstein, and the milking strain of Shorthorn. He believed the Jersey, or the Jersey crossed with the Ayrshire, was most favored amongst dairymen. All up-to-date dairymen agreed that the bull was of the utmost importance. He should be pure bred. Some people favored the dual purpose cow. For that purpose he would recommend Milking Shorthorn, or Ayrshire and Shorthorn cross. But he preferred specialising in milk and butter, as with the dual purpose cow one seldom secured a really first-class animal of either class. A cow should be broad across the hips, have thin withers, a fine neck, very full and bright eye, long thin tail, with very yellow skin on end. He liked to see a cow with a large paunch, with plenty of room to store her fodder, and no cow could continue giving large quantities of milk if she did not consume a large amount of feed. She should show large, well-developed milk veins under the belly. She should have a good-shaped udder, extending well forward—the further forward the better—teats well apart, and a good space between front and back teats. But escutcheon was the best indication of the cow's character. The longer, broader, and more plainly it appeared the better the cow. An idle cow needed a maintenance diet, so the cow that was milking needed a diet in comparison to what she did. They should weigh the milk, and use the Babcock test and discover the cows that they were feeding at a loss; and there were some in almost every breed. No one could ascertain the value of an animal's milk yield without recourse to the scales and tester, and this would be found a most interesting as well as profitable part of the dairyman's work. The cows should be put on a different paddock every few days. Milking machines were very useful when labor was scarce. Mr. W. H. Smith urged members to pay particular attention to the feeding of the cows. In reply to questions from Mr. Haynes, Mr. Hart said the calf should be left with its mother for a day or two after it was born. Pure-bred cows, as a rule, gave the best results. Other members participated in the discussion.

NARACOOORTE (Average annual rainfall, 22.60in.).

June 12th.—Present: 12 members and three visitors.

**SORREL: ITS HISTORY AND ERADICATION.**—Mr. J. M. Wray read a paper on this subject. Sorrel was one of the difficulties which the farmer had to face on the lighter soils of their district. There were two species, *i.e.*, swamp sorrel, named *Rumex acetosa*, and the species which preferred dry, sandy soils, *Rumex acetosella*, or sheep sorrel, the one that was commonly found in South Australia. It had a low, smooth-branched stem, and an underground creeping root stock. It was either annual or perennial, but generally the latter. In favorable situations it grew up to a foot in height, but usually from 3in. to 6in. above the surface. The leaves were shaped like an elongated arrow head, and were borne on long stalks. Stem leaves were stemless, small, and narrow. The male and female flowers were carried on different plants in branched leafless terminal heads. The plant flowered freely in summer and autumn. In late summer and early autumn the green foliage turned a red color, and the flower heads were also reddish. The small fruits were triangular and yellowish brown in color. The plants had an acid taste due to the presence of acid oxalates of potassium. Sorrel was related to rhubarb, and it had been used as a vegetable, but the acidity rendered it inferior as such, also as forage. It was a native of Europe, but now a common weed in most temperate climates. Its seed was a common impurity in grass and clover seeds, and it was probable through the importation of such that it was introduced here. It was known to be in Victoria in 1802, and finding it a suitable locality it, no doubt, followed close on the heels of the plough, and its dissemination was doubtless hastened by travelling live stock. Changing seed would also be a factor in this. Locally it would spread through its creeping habit of growth, and the dispersal of its abundant seed. It would grow well in good land, but not so well as other plants, whereas in poor land it gained the mastery over its competitors. For eradication four measures were proposed, *viz.*:—(1) Summer working; (2) smothering with a winter crop; (3) draining; (4) liming. Summer working should begin in ordinary seasons during the first summer month. In the case of land that was allowed to stand uncultivated for a year it would be necessary to feed it down in the spring in order to check all possibility of it going to seed. The land should be first ploughed, no matter how dry, and after being exposed to the heat of the sun for a week or more it should be cultivated and harrowed at different periods. In this manner the land became sweeter, thus reducing the food that gave to the sorrel such healthy growth. Sorrel lived but did not grow in the winter, and if the land was ploughed in the autumn and sown with a smothering crop like peas, the land would be covered with foliage before the sorrel was read to start growing. After harvest a little would come up on the stubble, but by ploughing the land as soon as the stock had cleaned it up, and then sowing with rye and oats in March for green feed, and following again with oats or wheat for hay, the sorrel would have had a good check, and meanwhile profitable returns would have been secured. Sorrel lived and grew to perfection on sour ground. Draining was one of the first things that must be done. When the land was well drained lime should be used freely in order to neutralise the acids that were present in the soil. The effect of lime on sorrel was vouched for by all the highest authorities in the agricultural world. Its repressing influence had been experienced in the sour, sandy soil near Mount Gambier. The presence of sorrel on arable land was a pretty sure sign of the absence of lime. Liming in the South-East had one set-back, and that was the cost. The amount of lime necessary at Kybybolite and thereabouts would probably be at least two tons per acre, so that to give it a fair trial meant the laying out of a considerable amount of capital. He did not hesitate to say that it was only a matter of a short time when liming in the South-East would be common practice. He would, therefore, suggest that farmers would do well to determine the approximate amount of lime a number of them would be likely to use and co-operate in the purchase. Mr. W. E. Rogers had had experience with sorrel in the Mount Gambier district 35 years ago, when summer fallow was recommended, but that did not prove a success. It was now spreading throughout the Hynam district, and he considered that lime was the best for eradicating the pest. Mr. S. Hart said that in the old country they had ceased the practice of using heavy dressings of lime, and were now giving the land a small dressing every two or three years, and he favored that practice. Mr. Bray considered that liming the land with heavy dressings

was too costly, and he favored summer working as the cheapest and best method of clearing the land. He suggested fallowing during the months of September and October, before the ground became too dry, and then working it back in the summer. Drainage was no good in sandy land, and that was where the sorrel grew the thickest. He also advised putting stable manure on thickly wherever possible. Mr. Feuerheerd said it was not always a sign that the land was sour because sorrel grew thereon, as he had some sweet land that had plenty of sorrel on it. The most effectual remedy was plenty of cultivation on hot days, and gathering up the roots wherever possible and destroying them. The Chairman (Mr. S. H. Schinckel) said that the most advantageous way to use lime was to give a fairly heavy dressing at the outset, and make the subsequent dressings lighter. Unless one had a proper distributing machine he favored the practice of putting the lime out in small heaps, slightly covering with earth, on a dull day, and then spreading it out in a few days when it would be slacked. Spring fallow and summer cultivation were among the best methods of getting rid of sorrel, but care had to be taken on some of the light soils, not to work the land too much, and into a powdery condition. After cultivating or harrowing he would put sheep on to eat out the roots, and remove them and put in a fresh lot of sheep if necessary. His experience of lime was that it stimulated the growth of sorrel at first, and then killed it. Drainage would be useless on such porous soil as at Mount Gambier, and yet sorrel was to be found in plenty on that rich land. Mr. Jenkins found that California lucerne would choke out the sorrel, and it was also a good fodder. Mr. Smith said that stable manure, if put on thickly at first, stimulated, and eventually killed the sorrel. For large areas he considered summer working the best. Lime acted really as an agent of the bacteria in the soil, making the plant food more available.

---

PENOLA (Average annual rainfall, 26.78in.).

June.—Present: nine members and one visitor.

DORADILLA VINE.—Mr. A. H. Strong read a paper giving particulars regarding this variety of grape vine. He said the history of the Doradilla in South Australia dated back about 77 years. The first lot of cuttings brought to South Australia by the settlers were not true to name, many being useless wild grapes. Dr. Kelly, however, returned to Spain, and secured some of the varieties they grew to-day. The Doradilla did not come into prominence until about 20 years ago, when several vignerons planted many acres with it. Previously to that time its value was not appreciated. At the present time hock, chablis, dry sherry, and brandy were manufactured from it. The Doradilla was a very vigorous grower, and very hardy. The grapes, too, had such thick skins that they could withstand the rough weather better than other varieties. The vine being later than others often escaped the early frosts, while the cost of picking was less. The Doradilla crop in South Australia would average about 4 tons per acre, and the Coonawarra district would produce from 6 tons to 8 tons per acre, if not more. When grown on irrigated land this variety contained too much moisture and not sufficient sugar to make wine. It was only good for brandy under such conditions.

KEITH, April 24th.—A paper on the selection of seed wheat was read by Mr. Shannon, and discussed by members.

PENOLA, March 6th.—PRIMARY PRODUCTS OF THE DISTRICT.—The Hon. Secretary (Mr. S. Ockley) said that his land (light loam), which was easily worked, and was retentive of moisture, was well adapted for the production of summer and autumn fodder crops for the maintenance of stock. Mr. Warner found the surest crops that could be grown on his soil (black plains) were oats and barley, which ranked as the most important in the rotation. Sheep were a necessity always. Mr. Darwent reported that he had sown oats and rape in spring, but the latter did not germinate till the following autumn.

# THE JOURNAL OF AGRICULTURE

## Published Monthly.

Subscription, 1s. per annum to residents in South Australia, and 2s. 6d. per annum elsewhere, including postage.

**Circulation, 7,100 Monthly.**

THE Journal contains information of an official character relating to the Agricultural Lands, Stock, and Produce Export Departments. Illustrated articles and paragraphs by Government experts dealing with all branches of agriculture, horticulture, viticulture, pastoral matters, dairying, stock diseases, poultry, etc., are published regularly.

The results of experiments in connection with methods of agriculture, etc., stock and poultry diseases, insect and fungoid pests in South Australia and other lands are recorded, as well as the results of work at Roseworthy Agricultural College.

The experience of members of the Agricultural Bureau is made available to subscribers by the publication of reports of meetings of the Branches, including the more important papers and the discussion on them.

The Inquiry Department of the Journal furnishes replies by Government experts to all questions sent in, and advice is given to beginners in agricultural industries.

The Reference Library of the Department of Agriculture, which contains so many valuable works on agricultural subjects and thousands of bulletins issued by Departments of Intelligence in all parts of the world, is at the disposal of subscribers during office hours.

Applications for enrolment on the subscribers' list should be addressed to the Department of Agriculture, Victoria Buildings, Victoria Square, Adelaide.

CLARENCE GOODE,

MINISTER OF AGRICULTURE.

## AGRICULTURE PUBLICATIONS.

The following publications have been issued by the Department, and are available for distribution at the prices mentioned:—

Vinegrowers' Manual, by A. Herland, 6d.; posted, 7d.

Reports of Conferences of Australian Fruitgrowers held at Brisbane and Wellington, 1s. each 1s. 1d. if posted.

**Journal of Department of Agriculture of South Australia**, 1s. per annum in advance; 3d. per single copy to residents of South Australia; 2d. per annum to other places.

Quinn's Pruning Book. Handbook for Fruit and Vine Growers; price, 2s. 6d.; posted, 3d.

Any of the following Bulletins or Leaflets may be obtained by sending a penny stamp for postage:—

Agriculture, Miscellaneous Agricultural Bureau Congress Reports; Amount of Spirits to be Extracted from a Ton of Raisins; Depth of Sowing of some Cultural Seeds; Digestibility and Handling of Wheat Hay; Farming Conference Reports; Feeding-Off Experiments with Sheep; Housebuilding in New Districts; Irish Potato Blight; Lucerne Cultivation and Management; Lucerne Leaf-Spot Disease; Lining Experiments; Reclamation of Land; Roseworthy College Germ Flocks; Roseworthy College Harvest Reports; Roseworthy College Experimental Field Reports; Sheep on the Farm; Spraying against Potato Blight; Stage to Cut Wheat Hay; Trifolium Stone-Gathering Machines.

Horticulture: Banded Bark Beetle; Bordeaux Mixture; Curculio Beetle; Codlin Moth Currant Industry; Fertilisation of Orchard Lands; Fruit Drying; Fruit Flies; Fruit Preserving; Grape Vine Mildews; Gummit Disease of Peach and Almond Trees; Selection and Planting of Fruit Trees; Peach Leaf Curl Fungus; Plums and Prunes; Preserving, Canning, and Drying of Fruits; Production of Early Tomatoes; Remedies for Diseases of Fruit Trees and Vines; Some Notes on Aphids.

Dairy: Milking of Cows; Spaying of Cows; Taints and Flavors of Dairy Produce; Bacteria in Milk and its Products; Testing Milk and Cream.

Stock: Branding of Cattle; Bot Flies and Bots; Castration of Colts and Spaying of Cows.

Poultry: Diseases of Poultry; Parasites of Poultry; Poultry Tick; Reports of the Egg-Laying Competitions; Single Testing for Egg Production.

Beekeeping Notes.

**[Every farmer and fruitgrower should join the Agricultural Bureau. Write to Department of Agriculture for particulars.]**
